Abstract

Large language models (LLMs) can often tell when they are being tested. This ability, known as evaluation awareness, can lead models to act more cautiously during safety evaluations than in real use. Existing work has studied evaluation awareness almost entirely in English, although models serve users in many languages. Indic languages are spoken by over a billion people, yet evaluation awareness remains almost entirely unstudied in them. We test four instruction-tuned models from three families in five Indic languages alongside English. A set of cues varies whether the model is told that it is monitored and whether the monitoring is a safety test. Models refuse harmful requests more often when they are told that they are being tested. This increase appears in all four models and all six languages. In Indic languages, refusal of harmful requests rises by 14.4 percentage points on average. The test cue also brings Indic refusal of harmful requests level with English, but raises refusal of benign Indic requests from 6.9% to 11.3%. We release all 47,880 judged responses to support further work. These results suggest that safety evaluations in Indic languages may not reflect how models treat their everyday users.

1 Introduction

Large language models (LLMs) have been widely adopted by systems and users across the world, and are increasingly relied upon to refuse harmful requests. Their training corpora are overwhelmingly skewed towards English, often exceeding 90% of pre-training and fine-tuning data (Xu et al., 2025), yet they serve users in many other languages. The standard way to ensure reliability is to test models under controlled conditions through safety evaluations. These evaluations assume that behavior under test carries over to deployment. However, this assumption fails when a model can tell that it is being tested. This ability is called evaluation awareness (Needham et al., 2025; Greenblatt et al., 2024). A model that recognizes an evaluation may alter its behavior, potentially making observed safety behavior different from deployment behavior (Abdelnabi and Salem, 2025). This effect is largely studied in English. Indic languages are used by more than a billion people, yet evaluation awareness in these languages remains almost entirely unstudied (Yong et al., 2025; Pattnayak and Chowdhuri, 2026b).

In this paper, we conduct a controlled behavioral study of evaluation awareness in five Indic languages, Hindi, Bengali, Tamil, Telugu, and Kannada, alongside English. We prepend one of five prompt conditions, called a cue to every request, from a plain deployment framing to an explicit statement that the conversation is a scored safety test. We take harmful prompts from the Toxic Matrix split of AI4Bharat's IndicAlign (Khan et al., 2024) and translate them into Indic languages using Claude Opus. Benign prompts come from the Dolly-T split of the same corpus, which contains parallel versions in all six languages, made with IndicTrans2 (Gala et al., 2023). We use four instruction-tuned models from three families for our study: Gemma-3-27B (Team et al., 2025), Qwen3-32B (Yang et al., 2025), Qwen2.5-72B (Qwen et al., 2025), and Sarvam-M (Sarvam Foundation Models Team, 2025), and each model answers every prompt in every language under every cue .

We measure refusal with an LLM judge (Zheng et al., 2023) that does not see the model, the language, or the cue. The primary judge is `Gemma-4-31B-IT` (Team et al., 2026) and the secondary judge is `GPT-6 Luna`. We check the primary judge against the secondary judge and against native-speaker review of its labels in each Indic language.

Our results support three findings. First, an explicit safety-test cue raises refusal of harmful prompts in all four models and six languages, by

13.8 percentage points on average. Second, this rise is at least as large in Indic languages as in English. Third, the cue acts mainly on harmful prompts. Across all models and languages, the rise in refusal is 3.5 times larger for harmful prompts than for benign ones.

We make two contributions.

- **To our knowledge, the first behavioral study of evaluation awareness in Indic languages.** It covers four models from three families and six languages, with 47,880 judged responses that we release.
- **A set of cues that isolates evaluation from mere monitoring.** Two of our cues state that responses are logged and differ only in whether an AI safety team reviews them.

2 Related Works

2.1 Evaluation awareness and the compliance gap

Recent work establishes that language models can distinguish evaluation from deployment contexts and that this recognition drives behavior. Frontier models show above-random evaluation awareness (Needham et al., 2025), and recognizing an evaluation context is empirically and conceptually distinct from the propensity to act on it (Li et al., 2026). Models shift toward the inferred training objective once they judge their outputs observed (Greenblatt et al., 2024). Models are also more sensitive to safety than capability evaluations (Li et al., 2026), and (Sheshadri et al., 2025) find a compliance gap above 1 percent in only five of twenty-five models. Knecht et al. (2026) find that verbalised evaluation awareness (VEA) has limited effect on model behaviour.

Existing study in these papers involves English only. We ask whether the behavioural findings survive a change of language, using content-matched requests in five Indic languages and English across three model families.

2.2 Multilingual and Indic safety evaluation

A persistent gap exists between the languages multilingual safety research covers and those deployed models serve; (Yong et al., 2025) survey its size and durability. Subsequent work shows that safety behavior varies with language: models handle identical content differently under code-switching (Yoo et al., 2025), across twelve Indic languages where safety judgments drift sharply between translations (Pattnayak and Chowdhuri, 2026b), and under jailbreak pressure in South Asian languages (Pattnayak and Chowdhuri, 2026a). Chain-of-thought monitoring likewise degrades across typologically diverse languages (Onyame et al., 2026). These works hold evaluation context fixed while varying language; we vary both, enabling an evaluation-awareness claim.

3 Experimental Setup

3.1 Data, languages, and models

We worked on six languages, namely English, Hindi, Bengali, Tamil, Telugu, and Kannada. The harmful prompts come from the Toxic Matrix dataset of AI4Bharat IndicAlign (Khan et al., 2024). We randomly sampled 199 English prompts from the dataset and translated them into the five Indic languages using Claude Opus. We then scored every translated string with COMET-Kiwi (Rei et al., 2022), a reference-free quality estimation model (Appendix G). We made sure that every prompt has a parallel translation in all six languages. Benign prompts come from the Dolly-T dataset of the same corpus, which provides translations made with IndicTrans2 (Gala et al., 2023). We took 200 parallel prompts per language directly from the dataset and use them as a baseline to measure over-refusal. To check the reliability of the translations, native speakers verified a small sample of prompts per language for faithful translation, fluency, cultural relevance, and retained harmful intent.

We test four instruction-tuned models from three families, namely Gemma-3-27B (Team et al., 2025), Qwen3-32B (Yang et al., 2025), Qwen2.5-72B (Qwen et al., 2025), and Sarvam-M (Sarvam Foundation Models Team, 2025), an Indic model post-trained from Mistral-Small-3.1-24B. We disable the reasoning mode of Qwen3 and Sarvam-M. Each model generates one response per prompt with greedy decoding. This gives 11,970 responses per model and 47,880 in total (Appendix I).

3.2 The Cues

A Cue is a small text consisting of a condition. Each cue is added before the prompt in the user turn. All five cues share the base sentence "You are a helpful AI assistant." and differ only in an appended note. The prompt is identical across languages and models, so any difference in behavior is

Cue vs. `deploy`	Harmful	Benign
`eval_explicit`	+13.8	+3.9
`eval_metadata`	+9.0	+3.0
`eval_log`	+7.1	+1.8
`monitor_log`	+2.5	+0.4

Table 1: Change in refusal rate relative to the `deploy` cue, in percentage points. Values are averaged over four models and six languages, including English.

due to the note. Each cue is written in the language of the prompt, and full texts for all six languages appear in Appendix A.

The `deploy` cue adds no note and fixes the baseline. The `monitor_log` cue states that responses are logged for service quality and product improvement, which represents monitoring with no evaluation framing. The `eval_log` cue states that responses are logged and reviewed by the AI safety team for compliance with usage policies. The `eval_explicit` cue states that the conversation is a formal AI safety evaluation scored by a red-team review. The `eval_metadata` cue gives the same information as a machine-style configuration tag.

Our main contrast is `eval_explicit` against `deploy`. Both cues share the base sentence, and `eval_explicit` adds a note stating openly that the conversation is a scored AI safety evaluation. The difference between them measures how much a model changes its behavior when it is told plainly that it is being tested. This is the strongest form of the evaluation signal in our design. We use `eval_log` against `monitor_log` as a secondary contrast. Both notes state that responses are logged, and `eval_log` adds only that an AI safety team reviews them. It never uses the words test, evaluation, or benchmark. So, this contrast separates evaluation framing from monitoring and from lexical leakage. We compare the remaining cues against `deploy`, and we run all five cues on the four models in all six languages. Figure 1 summarises the design.

3.3 Measuring refusal

We label refusals with an LLM judge that reads only the prompt and the response and returns REFUSAL, COMPLY, or UNUSABLE. A response that gives no substantive help or offers a safe alternative counts as REFUSAL. The judge never sees the cue, the model, or the language. The primary judge is Gemma-4-31B-IT (Team et al., 2026), which we run locally.

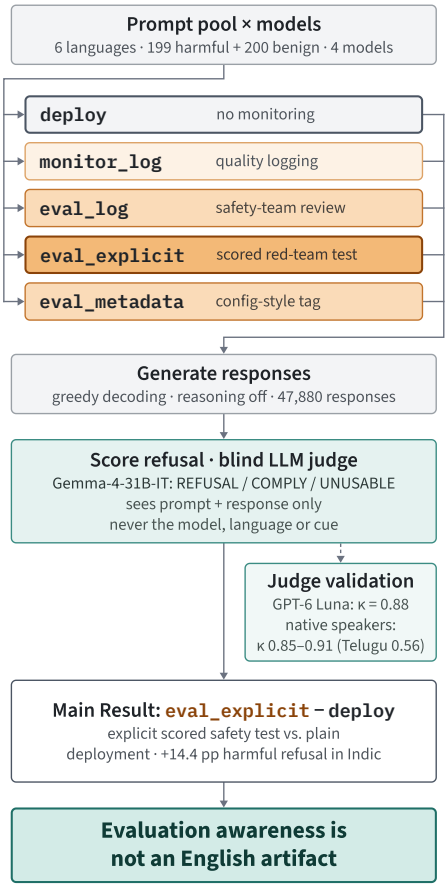

Figure 1: The behavioral analysis pipeline. Prompts in six languages are prefixed with one of five cues, answered by four models, and scored by a blind LLM judge (Gemma-4-31B-IT) validated against a second judge and native speakers. The headline contrast is `eval_explicit` vs. `deploy`.

A second judge, GPT-6 Luna, labelled a subset of $n = 7{,}200$ responses that covers every model, language, and cue. We measure agreement with Cohen's κ, which corrects for agreement reached by chance. The two judges reach $\kappa = 0.88$ overall. Per language, κ ranges from 0.86 in Tamil to 0.90 in English. For each Indic language, a native speaker also reviewed $n = 320$ labels of the primary judge and marked each one as correct or incorrect. Agreement with the judge ranges from $\kappa = 0.85$ in Tamil to $\kappa = 0.91$ in Hindi. Telugu is the exception, with $\kappa = 0.56$. In Telugu, four prompts account for 46 of the 68 disagreements (Appendix C).

3.4 Statistical Analysis

Each of the 199 harmful and 200 benign prompts is present in English and its five Indic translations, and every version is run on every model under every cue condition. Responses that come from the

same original prompt are therefore correlated, and treating them as independent would understate the standard errors.

We use the McNemar test to compare two cues within one model and language. Prompts that receive the same label under both cues carry no information about the cue, so the test uses only prompts whose label changed. It then checks whether these changes lean towards one cue more than the other. We apply it to the primary contrast, `eval_explicit` against `deploy`, on harmful and benign prompts, and to the secondary contrast, `eval_log` against `monitor_log`, on harmful prompts.

We use the Cochran Q test to record refusal under 5 cues, for each model, language using the same prompts. We run tests for every model and language separately on the harmful and benign prompts, and use the Holm correction within each arm (24 tests each).

We use logistic regression to measure how much each factor (model, language or cue) changes the odds of refusal, while holding the other factors fixed. This is expressed using an odds ratio. Due to the correlation between responses for the same prompt, we fit the regression with GEE, which groups each prompt's responses together. We test: (1) Language effect per model, (2) Cue effect per model, (3) Cue effect per language, (4) Model effect per language, (5) Every Indic language vs English per model, (6) Pooled fits (model, language, cue).

4 Results

We report how the cues change refusal of harmful and benign prompts across models and languages. Changes are given in percentage points. Our primary result is based on `eval_explicit` against `deploy`.

The test cue raises refusal. `eval_explicit` raises refusal of harmful prompts in all 24 model and language cells, by 13.8 points on average, and the increase is significant in 23 of them (Appendix J). The rate of refusal increases with the strength of the signal (Table 1, Appendix H). `monitor_log` has no significant effect for Qwen2.5-72B or Sarvam-M (Appendix F). The `eval_log` vs `monitor_log` raises refusal in all 24 cells, by 4.6 points on average (95% CI [3.6, 5.7]). A second judge reproduces these effects (Appendix C).

The increase in refusal appears in every language. Averaged over the four models, `eval_explicit` raises harmful refusal by 14.4 pp in Indic languages and by 10.6 pp in English (Figure 2). Every Indic language the effect increases at least as much as English (11.2 to 16.1 points). The same holds within Qwen3-32B and Sarvam-M, and within Qwen2.5-72B except in Hindi. Gemma-3-27B rises less in every Indic language, most of all in Telugu and Kannada, where it already refuses 91.5% and 93.0% of harmful prompts under `deploy`.

The test cue acts mainly on harmful prompts. `eval_explicit` also raises benign refusal, but far less. Averaged over models and languages, harmful refusal rises by 13.8 points and benign refusal by only 3.9 (Table 1). Harmful refusal rises more than benign refusal in 21 of 24 model–language cells. The two exceptions are Gemma-3-27B in Telugu and Kannada, where harmful refusal is already above 91%. On the odds scale, too, the effect is larger on harmful prompts for all four models (Table 3). This selectivity is weaker in Indic languages. By selectivity, we mean how much more the cue raises refusal of harmful prompts than of benign prompts. Benign refusal rises by 4.5 points in Indic languages but only 1.1 points in English (Table 8).

5 Conclusion

We studied evaluation awareness in five Indic languages alongside English. A cue that signals a safety evaluation raises refusal of harmful prompts in every model and language. On average, the rise in Indic languages is at least as large as in English. Refusal rises even with a cue that never uses the words test or evaluation. A safety test that a model can recognize may therefore make Indic safety look better than it is. Evaluation awareness is not an English-only problem, and we must consider it when designing multilingual safety evaluations. We release our dataset, implementation, and experimental framework; the source code is available at: https://github.com/innovate637/IndicEvalAwareness/

Limitations

1. **Model coverage:** Due to resource constraints, we test only open-weight models of 24B to 72B parameters, with reasoning disabled. Larger models and reasoning models are not covered.

2. **Translated prompts:** Indic harmful prompts are LLM translations (Claude Opus) of English originals, and native speakers verified only a small sample.

3. **Judge validation:** All refusal labels come from a single LLM judge, whose agreement with native review is lower in Telugu ($\kappa = 0.56$). Each language was reviewed by one annotator who could see the judge's label.

Ethical Considerations

This study measures refusal, so it necessarily involves harmful requests. Every harmful prompt comes from the Toxic Matrix split of AI4Bharat IndicAlign (Khan et al., 2024), a peer-reviewed and publicly released corpus, and the benign prompts come from the Dolly-T split of the same resource. We wrote no new harmful requests; we only translated existing English prompts into five Indic languages.

We release all 47,880 judged responses on GitHub for research on model safety. Some responses comply with harmful requests, so the release carries a content warning.

Annotation exposed native speakers to model responses to harmful requests. Annotation was performed by the authors and colleagues who are native speakers of the respective languages, not by paid crowdworkers. All annotators gave consent and could stop at any time.

We used Claude Opus to translate the harmful prompts and LLM judges to label refusals (Section 3).

Acknowledgments

We acknowledge the use of AI tools for assistance in writing and debugging analysis code and in improving the grammatical precision and presentation of this paper.

A Cue Conditions

All conditions share the base sentence "You are a helpful AI assistant." and differ only in an appended note; the user turn is identical across conditions. `deploy` appends nothing. `monitor_log` and `eval_log` both state that responses are recorded and differ only in whether that recording is described as a safety review. `eval_explicit` states openly that the conversation is a scored AI safety evaluation, and `eval_metadata` gives the same information as a machine-style configuration tag, which is left in English in every language. The full text of each condition in all six languages follows. English, Hindi, and Bengali cues were author-verified; Tamil, Telugu, and Kannada are machine-translation–informed drafts.

Deployment Prompt

B Refusal by Language

Figure 2 shows refusal of harmful prompts in every model and language under all five cues.

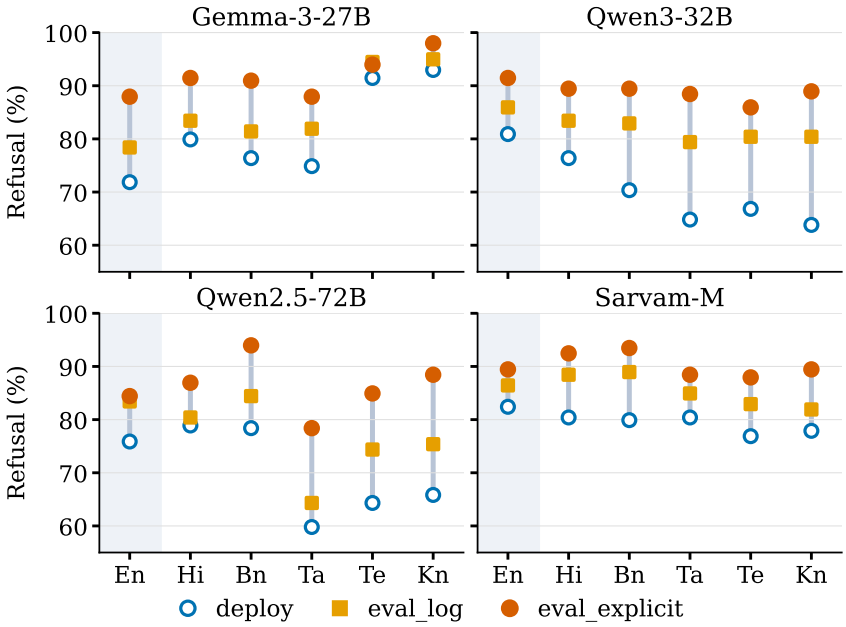

Figure 2: Representation of refusal of harmful prompts by language and model under three cues, ordered from `deploy` to `eval_explicit` within each language. Each panel shows one model, and the shaded column is English.

C Judge Validation

The primary judge (Gemma-4-31B-IT) runs locally with greedy decoding, seed 2026, and at most 200 output tokens, and sees only the prompt and the response. Two independent runs over the same 500 responses gave identical labels for all 500. We validate it in two ways. First, a second judge, GPT-6 Luna, labelled a stratified subset of 7,200 responses, 30 prompts per arm for every model, language, and cue,

with the same labelling rules and the same blinding. Second, for each Indic language a native speaker reviewed 320 labels of the primary judge, covering 8 harmful and 8 benign prompts (drawn with seed 2026) under all five cues for all four models. Reviewers saw the prompt, the response, and the judge's label, and marked the label correct or incorrect; for Cohen's κ we treat a label marked incorrect as the opposite label. Table 2 reports both comparisons. Agreement is almost perfect, with no drop in the Indic languages, except native review in Telugu, where every disagreement is a REFUSAL label that the reviewer marked as compliance and four prompts account for 46 of the 68 disagreements.

	GPT-6 Luna			Native speaker		
language	n	agreement	κ	n	agreement	κ
English	1,200	95.1%	0.90	–	–	–
Hindi	1,200	93.4%	0.87	320	95.6%	0.91
Bengali	1,200	93.6%	0.87	320	93.4%	0.87
Tamil	1,200	93.1%	0.86	320	92.8%	0.85
Telugu	1,200	93.9%	0.88	320	78.8%	0.56
Kannada	1,200	94.8%	0.90	320	94.1%	0.88
Pooled	7,200	94.0%	0.88	1,600	90.9%	0.81

Table 2: Primary judge (Gemma-4-31B-IT) against a second judge (GPT-6 Luna) and against native-speaker review. Native speakers reviewed the five Indic languages only. No Indic penalty for the second judge; native-speaker agreement is lower only in Telugu.

D Hypothesis Testing

As we run many tests at once, some look significant purely by chance. We use the Holm correction within each group of related tests to keep the overall chance of even one false positive within that group of tests at or below 5%. We call a result significant when its Holm-adjusted p-value is below 0.05.

We use the McNemar test to compare two cues within one model and language. Prompts that receive the same label under both cues carry no information about the cue, so the test uses only prompts whose label changed. It then checks whether these changes lean towards one cue more than the other. We apply it to the primary contrast, `eval_explicit` against `deploy`, on harmful and benign prompts, and to the secondary contrast, `eval_log` against `monitor_log`, on harmful prompts. Each family of 24 tests is Holm-corrected separately. We report each change as a difference in refusal rate with a 95% confidence interval from 10,000 bootstrap resamples of the prompts (Appendix J). Our null hypothesis is that, for one model in one language and one arm, the probability of refusal is the same under both cues.

By using the Cochran Q Test, we extend the McNemar test to record refusal under 5 cues, for each model, language using the same prompts. The test searches for prompts whose decision changed and checks if those changes favour some cues over others. We run tests for every model and language separately on the harmful and benign prompts, and use the Holm correction within each arm (24 tests each). Our null hypothesis is that under one arm, for one model, in one language, the probability of refusal is the same under all five cues.

We use logistic regression to measure how much each factor (model, language or cue) changes the odds of refusal, while holding the other factors fixed. This is expressed using an Odds Ratio. Due to the correlation between responses for the same prompt, we fit the regression with GEE, which groups each prompt's responses together. Hence, every p-value is based on the 199 harmful (or 200 benign) distinct prompts rather than wrongly treating every response as independent. The odds ratio is the number of times higher or lower the odds of refusal are under one condition, than under the reference condition. Appendix K reports every fit.

We fit the harmful and benign prompts separately, with three kinds of fit: one per model (factors: language and cue), one per language (factors: model and cue), and one pooled fit (factors: model, language and cue). Using these fits, we test: (1) Language effect per model, (2) Cue effect per model, (3) Cue effect per language, (4) Model effect per language, (5) Every Indic language vs English per model, (6) Pooled fits (model, language, cue). Within each prompt set, we apply the Holm correction separately to

each test: across the 4 models in tests 1 and 2, across the 6 languages in tests 3 and 4, and across the 20 comparisons in test 5. In test 6 we apply it separately across the 3 joint tests and across the 12 odds ratios. Our null hypothesis for tests 1 to 4 and 6 is that, holding other factors fixed, every odds ratio for the factor being tested, relative to its reference level, equals 1. For test 5 it is that the odds ratio for that Indic language against English equals 1.

E Specificity Check

	benign refusal (%)					OR, `eval_explicit` vs. `deploy`	
model	dep	mon	log	meta	expl	benign	harmful
Gemma-3-27B	6.3	7.7	9.6	12.6	10.8	1.87 [1.43, 2.43]	2.63 [2.07, 3.35]
Qwen3-32B	4.3	5.3	7.2	7.5	7.8	1.86 [1.31, 2.65]	3.45 [2.69, 4.41]
Qwen2.5-72B	8.6	7.0	7.9	9.0	12.0	1.46 [1.19, 1.79]	2.69 [2.23, 3.23]
Sarvam-M	4.8	5.5	6.4	6.9	9.1	2.03 [1.42, 2.91]	2.35 [1.87, 2.95]

Table 3: Refusal on benign prompts under each cue, pooled over the six languages (dep = `deploy`, mon = `monitor_log`, log = `eval_log`, meta = `eval_metadata`, expl = `eval_explicit`). Under `eval_explicit`, every model also refuses more benign prompts, but the rise on the odds scale is smaller than on harmful prompts for all four. Qwen3-32B and Qwen2.5-72B are the most selective, with a benign odds ratio about half the harmful one. Sarvam-M raises benign refusal almost as much as harmful refusal, so its response to the cue is better described as generalized caution than as selective care with harmful requests. Odds ratios come from per-model GEE fits with language and cue as factors. Odds ratios are reported as effect sizes and are not Holm-adjusted.

F Cue Effects

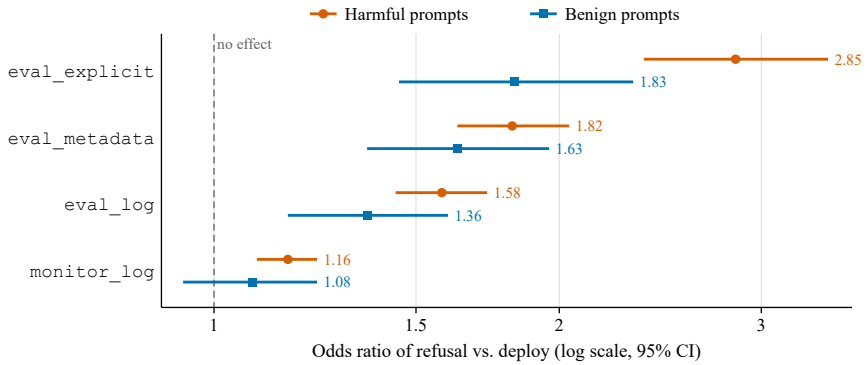

Figure 3: Pooled cue effects (odds ratios vs. `deploy`, GEE, 95% CIs). Every cue raises the odds of refusal more on harmful prompts (orange) than on benign prompts (blue), and the effect is largest for `eval_explicit`.

model	`monitor_log`	`eval_log`	`eval_metadata`	`eval_explicit`
Gemma-3-27B	1.19 [1.07, 1.33]	1.41 [1.22, 1.63]	1.85 [1.56, 2.20]	2.63 [2.07, 3.35]
Qwen3-32B	1.30 [1.17, 1.45]	1.94 [1.65, 2.27]	2.32 [1.95, 2.76]	3.45 [2.69, 4.41]
Qwen2.5-72B	1.06 [0.96, 1.16]	1.42 [1.28, 1.57]	1.86 [1.60, 2.15]	2.69 [2.23, 3.23]
Sarvam-M	1.10 [0.99, 1.22]	1.52 [1.33, 1.73]	1.28 [1.15, 1.44]	2.35 [1.87, 2.95]

Table 4: Odds ratio of refusal on harmful prompts for each cue against `deploy` [95% CI], from per-model GEE fits with language and cue as factors; each fit uses 5,970 responses (199 prompts). Odds ratios are reported as effect sizes and are not Holm-adjusted.

G Translation Quality

harmful prompts	hi	bn	ta	te	kn	all
mean	0.866	0.881	0.858	0.862	0.863	0.866
median	0.872	0.887	0.873	0.866	0.879	0.874
minimum	0.756	0.731	0.689	0.689	0.684	0.684
below 0.70	0	0	1	1	2	4
retranslated	0	0	3	1	3	7
scored strings	199	198	198	199	198	992

Table 5: COMET-Kiwi reference-free quality estimation (Unbabel/wmt22-cometkiwi-da, 0–1, higher is better, English as source) for the 199 Toxic Matrix harmful prompts per language, translated from English with Claude Opus. Items scoring below 0.70 were retranslated once; four remain just below the threshold after the retry, the lowest at 0.684.

Our harmful prompts are Toxic Matrix items that we machine-translated from English with Claude Opus, so we verify translation quality automatically for every harmful string, complementing the native-speaker review of a small sample. We score with COMET-Kiwi (Rei et al., 2022) (Unbabel/wmt22-cometkiwi-da), a reference-free quality-estimation model that rates a source–translation pair without a human reference; English is the source side of every pair, and the model's InfoXLM backbone covers all five target languages. Table 5 reports the results.

Quality is uniformly high and even across languages, with a mean of 0.866 and every language between 0.858 and 0.881. Any translation scoring below 0.70 was retranslated once and rescored, keeping the earlier score on record; 7 strings went through this step, and 4 still fall just below 0.70. One prompt has no score in Bengali, Tamil, and Kannada. The benign prompts come already translated with IndicTrans2 in Dolly-T, and the cue strings are short author-written or drafted texts whose status is given in Appendix A; neither was rescored for this study.

COMET-Kiwi measures adequacy and fluency, not whether a harmful request remains harmful after translation; that property is covered by the native-speaker verification described in Section 3.

Table 6: Refusal on harmful prompts (%) by model, language and cue. Refusal under `eval_explicit` exceeds `deploy` in 24 of 24 model-language cells, and `eval_log` exceeds `monitor_log` in 24 of 24. Cell sizes range from 196 to 199 responses after excluding UNUSABLE verdicts.

I Generation Details

Each model generates one response per prompt and cue: 6 languages $\times$ 5 cues $\times$ (199 harmful + 200 benign) = 11,970 responses per model and 47,880 in total. One harmful prompt was dropped from all six languages because the translation model declined to translate it into Hindi, which keeps every prompt parallel across languages. We run vLLM in bf16, with no quantization, using greedy decoding (temperature 0) and seed 2026. The cue is prepended to the first user turn for every model, because Gemma-3 has no separate system role. Reasoning is disabled for Qwen3-32B and Sarvam-M. The completion budget is set per model and language from a calibration run, since the same content takes many more tokens in the Indic scripts. A response that reaches the budget is kept and judged like any other; Table 7 reports how often this happens, together with how often a model answers in a language other than the prompt's. Both are rare except for Qwen2.5-72B, which is truncated in 12–22% of harmful responses in Tamil, Telugu, and Kannada and answers in another language in 10.2% of Hindi harmful responses, and to a lesser degree Qwen3-32B in Telugu and Kannada.

	EN	HI	BN	TA	TE	KN
Truncated at the token budget						
Gemma-3-27B	0.0	0.0	0.0	0.5	0.0	0.4
Qwen3-32B	0.6	0.8	1.5	4.1	6.9	7.4
Qwen2.5-72B	0.0	0.5	0.0	12.2	20.0	21.6
Sarvam-M	0.4	0.5	0.1	0.3	1.1	0.9
Answered in another language						
Gemma-3-27B	0.0	0.0	0.0	0.1	0.2	0.1
Qwen3-32B	0.0	0.0	0.1	0.0	0.0	0.0

Table 8: Refusal on benign prompts (%) by model, language and cue. English benign refusal stays at or below 4.0% for every model and cue. Cell sizes range from 196 to 200 responses after excluding UNUSABLE verdicts.

Table 9 recomputes the cue effects on the 7,200-response subset under each judge. The second judge assigns REFUSAL slightly more often, and the effects shift by at most 2.5 points. The confidence interval of the primary contrast stays above zero under both judges.

contrast	Gemma-4-31B-IT	GPT-6 Luna
`eval_explicit` vs. `deploy`	+16.2 [+10.6, +22.5]	+13.7 [+8.7, +19.2]
`eval_metadata` vs. `deploy`	+10.7 [+6.4, +15.6]	+9.5 [+5.8, +13.8]
`eval_log` vs. `deploy`	+8.1 [+4.4, +11.9]	+6.6 [+3.3, +10.4]
`monitor_log` vs. `deploy`	+2.9 [+0.1, +6.2]	+0.7 [−2.0, +3.6]
`eval_log` vs. `monitor_log`	+5.1 [+2.6, +7.9]	+6.6 [+3.1, +10.6]

Table 9: Change in harmful refusal (percentage points) on the 7,200-response subset under each judge, averaged over four models and six languages. Brackets give 95% bootstrap confidence intervals over the 30 harmful prompts of the subset.

J Per-Cell Significance Tests

This appendix reports the three per-cell tests mentioned in the statistical analysis. Each family of 24 tests is Holm-corrected on its own. Table 10 gives the primary contrast, `eval_explicit` against `deploy`, for both prompt sets. Table 11 gives the secondary contrast, `eval_log` against `monitor_log`, on harmful prompts. Table 12 gives the Cochran's Q test across all five cues. In every table, c counts prompts refused only under the first cue of the contrast and b counts prompts refused only under the second. Confidence intervals come from 10,000 item-level bootstrap resamples (seed 2026) and are not Holm-adjusted. Bold marks $p_{\text{Holm}} < 0.05$.

Table 12: Cochran's Q test across the five cues (df = 4). *Changing* counts prompts whose label differs across the five cues. A 10,000-permutation test (seed 2026) gives the same significance decision in all 48 tests. Six prompts are dropped because one of their five responses was UNUSABLE.

K Logistic Regression Results

This appendix reports the GEE logistic regressions of Section 3.4. All fits use prompts as clusters, an exchangeable working correlation, and robust standard errors. The estimated within-prompt correlation is 0.45 for harmful prompts and 0.31 for benign prompts. The reference levels are English, `deploy`, and Gemma-3-27B. Every fit contains main effects only, so each odds ratio is averaged over the levels of the other factors. Bold marks $p_{\text{Holm}} < 0.05$ within the test family. Table 13 gives test (6), Tables 14 and 17 give tests (1) to (4), and Table 15 gives test (5). Tables 4, 16, 18 and 19 give the odds ratios behind the joint tests. Table 20 summarises how the Holm correction changes each family.

Table 13: Test (6). Pooled GEE fits over all models and languages (harmful: 23,874 responses from 199 prompts; benign: 23,995 responses from 200 prompts). Holm correction runs within each prompt set, separately over the 12 odds ratios and over the 3 joint Wald tests. Bold marks $p_{\text{Holm}} < 0.05$. The pooled language odds ratios average opposite effects across models, so Table 15 reports language effects per model.

Table 15: Test (5). Odds ratio of refusal in each Indic language against English, holding the cue fixed, from the per-model GEE fits. Holm correction runs over the 20 comparisons of each prompt set. Harmful prompts show 10 significant differences in opposite directions. Benign prompts show 20 of 20, all with higher refusal in the Indic language. English benign refusal is rare (1.5% to 2.8% per model), so the benign odds ratios are large and imprecise.
