Figure 1: Geographic coverage of CARDAMOM across six countries: Egypt, Jordan, Lebanon, Mauritania, Palestine, and Saudi Arabia. The corpus covers 21 micro-dialects spanning urban, rural, and regional varieties.

Abstract

We present CARDAMOM, a micro-dialectal Arabic speech dataset designed to support fine-grained evaluation and adaptation of automatic speech recognition (ASR) systems. Community-curated by native speakers familiar with the represented varieties, CARDAMOM contains approximately 40 hours of transcribed YouTube speech spanning 21 micro-dialects across Egypt, Jordan, Lebanon, Mauritania, Palestine, and Saudi Arabia. Each segment is annotated with one or more operational micro-dialect labels, code-switching information, and utterance-level perceived gender, enabling analysis of sub-country variation that is obscured by conventional country-level labels. We describe the collection and annotation process, motivate the micro-dialect inventory linguistically, and benchmark four multilingual ASR

systems in zero-shot and adapted settings. The strongest zero-shot system obtains 43.47% aggregate WER, with particularly high error rates on Mauritanian and Lebanese varieties; adaptation on CARDAMOM reduces its WER to 35.21%. Audio-based identification experiments further show that the annotations provide a learnable prediction target, with a dedicated classifier reaching 85.57% accuracy on 21-way micro-dialect identification. CARDAMOM provides a resource for studying localized dialectal variation and developing Arabic speech systems with broader regional coverage.¹

1 Introduction

Arabic speech technologies have advanced rapidly, yet performance remains uneven across Modern

¹CARDAMOM anonymized repository: <https://github.com/cardamom-paper/Cardamom-data>.

Standard Arabic (MSA) and the regional dialects that dominate everyday communication (Sullivan et al., 2026; Alqadasi et al., 2025; Alsayadi et al., 2022). Although MSA is widely used in education, official communication, and formal media, spoken interaction across the Arab world is primarily dialectal. These dialects encode historical, cultural, social, lexical, phonetic, and prosodic patterns, creating substantial variability for automatic speech recognition (ASR) and related speech processing tasks (Talafha et al., 2025; Djanibekov et al., 2025).

Recent multidialectal corpora, such as Casablanca (Talafha et al., 2024) and SADA (Alharbi et al., 2024), have expanded coverage across major varieties. However, most existing resources still represent dialects at relatively coarse regional or national levels, leaving fine-grained sub-country variation under-represented. In this work, we employ the term *micro-dialect* to refer to a localized sub-country variety associated with specific speech communities and reflected in systematic phonetic, lexical, or prosodic patterns. This granularity is important since intra-country variation can be substantial and hence country-level labels may obscure speech continua shaped by geography, contact, migration, and local identity (Al-Wer, Enam, 2002). This gap motivates the development of Arabic speech resources that move beyond broad dialectal labels and make localized variation observable. Such resources are essential for testing whether speech models generalize across nearby but distinct communities, identifying varieties that remain underserved, and developing ASR systems that are robust to Arabic as it is actually spoken.

We address this need with CARDAMOM, a community-driven Arabic speech corpus designed for fine-grained analysis of micro-dialectal variation. The corpus spans localized varieties in *Egypt, Jordan, Lebanon, Mauritania, Palestine, Saudi Arabia*. Rather than relying only on broad country-level dialect labels, CARDAMOM is curated and annotated by native speakers familiar with the relevant local varieties. The data are drawn from publicly available YouTube videos and transcribed to support ASR evaluation in real-world speech conditions. Overall, CARDAMOM contains ~40 hours of transcribed speech across 21 micro-dialects, together with speaker-level metadata such as gender. This design enables evaluation of ASR and dialect identification at both country and micro-dialect levels, making it possible to examine where (and, if so, to what extent) current speech models may still

be struggling, and which localized Arabic varieties remain poorly served.

The contributions of this study are: (i) *We introduce CARDAMOM, a micro-level multidialectal Arabic speech dataset* containing 40 hours of transcribed speech from localized varieties across six countries. (ii) *We provide high-granularity micro-dialect annotations* covering 21 local varieties, enabling evaluation beyond coarse country-level dialect categories. (iii) *We release speaker-level metadata, including gender*, to support detailed analysis of Arabic speech technologies across sociolinguistically diverse conditions.

2 Related Work

Arabic Speech and ASR Resources. Arabic ASR has benefited from large broadcast and web-derived corpora, including NIST EARS (Pallett, 2003), DARPA GALE (Soltau et al., 2009), and the MGB Challenge series (Ali et al., 2016, 2017, 2019), which supported multi-dialect broadcast ASR, Egyptian Arabic YouTube speech, and dialect identification across Arabic-speaking countries. Later resources such as QASR (Mubarak et al., 2021), MASC (Al-Fetyani et al., 2023), Aswat (Alkanhal et al., 2023), and SADA (Alharbi et al., 2024) further expanded Arabic speech data.

Dialectal, Multidialectal, and Fine-Grained Arabic ASR. Recent resources and shared tasks have expanded dialectal Arabic speech processing, including Casablanca (Talafha et al., 2024), NADI 2025 (Talafha et al., 2025), ADI-20 (Elleuch et al., 2025), and focused low-resource corpora such as TuniFra (Choux et al., 2025). At the same time, work on text-based Arabic dialect identification has shown that variation can be modeled below the country level (Abdul-Mageed et al., 2018, 2020). However, spoken resources remain mostly organized around countries or broad regional varieties (Ali et al., 2019; Talafha et al., 2024, 2025; Elleuch et al., 2025), leaving fine-grained micro-dialectal supervision underrepresented in Arabic ASR.

Code-Switching, Orthography, and Transcription Challenges. Arabic ASR technology also need to handle code-switching, mixed orthographies, and non-standardized dialectal spelling. Mixat (Al Ali and Aldarmaki, 2024) and ZAEUBC-Spoken (Hamed et al., 2024) address bilingual Arabic-English speech, Casablanca includes code-switching annotations in a multidialectal ASR setting (Talafha et al., 2024), and

CAFE targets spontaneous code-switching in North African Arabic (Lachemat et al., 2025). PolyWER (Kadaoui et al., 2024) and Arabic ASR diacritization work (Aldarmaki and Ghannam, 2023) further show that transcription and evaluation choices are critical under script, transliteration, and dialectal variation.

Modeling and Benchmarking. Large multilingual models such as Whisper (Radford et al., 2023), MMS (Pratap et al., 2024), and SeamlessM4T (SEAMLESS Communication Team, 2025) are common ASR baselines, but Arabic-specific work shows that dialectal variation, unseen dialects, code-switching, and data imbalance remain challenging (Talafta et al., 2023; Djanibekov et al., 2025). Recent work addresses these issues through Whisper adaptation for multidialectal Arabic ASR (Özyilmaz et al., 2025), Arabic-focused models such as VoxArabica (Waheed et al., 2023), Habibi (Chen et al., 2026), ArTST (Toyin et al., 2023), and shared evaluation through the Open Universal Arabic ASR Leaderboard (Wang et al., 2025).

Despite these advances, most Arabic speech resources still rely on broad regional or country-level dialect labels. CARDAMOM addresses this gap with ~40 hours of transcribed speech labeled across 21 micro-dialects, enabling fine-grained evaluation of within-dialect variation and cross-micro-dialect generalization in Arabic ASR. A more detailed discussion of related work is provided in Appendix A.

3 Dataset Description

Data Source and Selection We collect naturally occurring speech from publicly available YouTube videos covering localized varieties in *Egypt*, *Jordan*, *Lebanon*, *Mauritania*, *Palestine*, and *Saudi Arabia*. We prioritize non-scripted, non-read speech, including interviews, vlogs, and informal discussions, to capture conversational dialect use across styles, speaker variation and recording conditions, including naturally occurring code-switching. To construct the micro-dialect inventory for each country, we first elicited candidate local varieties from native speaker annotators based on their linguistic and geographic knowledge.² Highly similar or hard-to-distinguish candidates were consolidated into a broader category to reduce label redundancy. Annotators then curated source metadata by assigning YouTube URLs to the corre-

sponding micro-dialect categories, using the dominant variety (the one used for most of the speech content) when a video contained more than one. This source-level assignment organized collection, while final micro-dialect labels were assigned at the segment level and could include multiple labels when an utterance was compatible with more than one local variety. The resulting inventory broadly reflects within-country geographic variation: larger countries such as *Saudi Arabia*, *Egypt*, and *Mauritania* have more geographically dispersed micro-dialect regions, while the smaller, more contiguous Levantine countries (*Jordan*, *Palestine*, *Lebanon*) show comparatively fewer localized categories.

Release Format. We release CARDAMOM as standoff annotations rather than redistributed audio: for each utterance we release the source YouTube video ID together with our human-produced transcription, micro-dialect label(s), perceived gender, code-switching status, and start/end timestamps, along with code to reconstruct the corpus by fetching the corresponding audio from the original video IDs. We do not release nor redistribute audio. Further release and licensing details are provided in the Ethics and Data Statement.

Segmentation After collecting the audio, we segmented recordings into annotation units of at most 20 minutes, chosen to keep annotation tasks manageable, maintain interface stability during upload and playback, and facilitate navigation, while preserving the source-level micro-dialect label.

Team Members All annotations are carried out by team members who are also co-authors of the current work. All team members are native speakers from the Arab world, fluent in their country-level dialects and at least one corresponding micro-dialect each. In total, the team is comprised of 31 members: 5 for Egypt, 8 for Jordan, 2 for Lebanon, 4 for Mauritania, 3 for Palestine, and 9 for Saudi Arabia. Each members primarily annotated speech from their own micro-dialect, while also being able to annotate other micro-dialects from the same country when needed. Table 8 (Appendix E) breaks these totals down by micro-dialect. Counts are not mutually exclusive: some members were fluent in more than one micro-dialect and annotated material from multiple varieties, so summed coverage can exceed a country’s participant count. Likewise, an utterance can receive more than one micro-dialect label when it shares features across local varieties (Section 6.2).

²We use *micro-dialect* to denote a fine-grained sub-variety of a broader dialect (Abdul-Mageed et al., 2020).

4 Annotation Tasks and Guidelines

4.1 Overview

All annotation tasks were uploaded to Label Studio³ (Tkachenko et al., 2020) and organized by country. Annotators were provided with written guidelines⁴ describing the tasks, labeling criteria, and examples for each label type, refined iteratively through weekly online team meetings, with a dedicated Slack channel for coordination and discussions.

We annotate each speech segment using a unified segment-level schema designed to support ASR, Arabic dialect identification (ADI), micro-dialect analysis, code-switching analysis, and aggregate analysis by speaker-level metadata.

4.2 Annotation Protocol

As illustrated in Figure 2 (Appendix E), annotators provide, for each segment: (i) transcription reflecting the spoken form as it is typically written in everyday communication; (ii) country-level dialect label and one or more micro-dialect labels; (iii) perceived speaker gender; (iv) a code-switching indicator; (v) start and end timestamps. For code-switched segments, annotators also provide two transcript variants, one with foreign words rendered in Arabic script and another in Latin script. The main annotation tasks are described below.

4.2.1 Task 1: Segment Selection

Annotators select candidate segments from long-form videos using a pre-defined set of labels, including micro-dialect labels for dialect-specific content (e.g., in Egypt: Alexandrian, Cairene, Port Saidi, and Saidi) and MSA. Each selected segment must: (i) contain speech from a single speaker with no overlap; (ii) be audibly clear and transcribable, allowing for mild background noise; (iii) contain at least one word and preferably be no longer than 30 seconds; and (iv) capture a complete utterance with intact boundaries, including the full phonetic material of the first and last words.

Each segment is assigned at least one micro-dialect label when it contains dialectal speech, and more than one when it plausibly belongs to multiple micro-dialects. For example, the Jordanian utterance *مأشي ولا يهيمك* (*māshi walā yihimmak*, ‘okay, no

worries’) can be realized in both Falahi and Madani varieties; in such cases, both labels are applied.

4.2.2 Task 2: Transcription

Arabic dialects lack a single standardized writing system, so annotators transcribe the audio using a natural written form reflecting how the relevant dialect is commonly written in everyday communication, prioritizing fidelity to the speech signal over normalization to MSA. Annotators are encouraged to use standard Arabic orthographic markers when appropriate (e.g., hamza and tanwin) and to write numbers alphabetically to preserve inflectional and contextual realizations.

For code-switching (CS), annotators provide two transcript variants: (i) a version in which foreign words are rendered in Arabic script, and (ii) a version in which foreign words are rendered in Latin script.

4.2.3 Task 3: Speaker Gender

Annotators label speaker gender using the available label set {*male*, *female*}. These labels are based on annotators’ perception from the speech signal and are intended only for aggregate analysis of model performance and dataset composition. They are not intended to identify speakers or make claims about speakers’ self-identified gender.

4.3 Quality Control

Annotators followed shared written guidelines and discussed ambiguous cases with the project team during regular coordination meetings. We also manually inspected completed annotations for transcription completeness, segment boundary quality, single-speaker constraints, and consistency between country-level and micro-dialect labels, resolving ambiguous cases through discussion with annotators familiar with the relevant local varieties. This was intended to ensure that the released labels reflect both the acoustic content of the segment and the sociolinguistic knowledge of native-speaker annotators.

5 Micro-Dialects Overview

Arabic dialects exhibit substantial regional and social variation, and broad national labels often obscure the localized varieties that speakers use in everyday communication (Jarrar et al., 2023; Holes, 2004; Procházka, 2021; Zaidan and Callison-Burch, 2014). For this reason, CARDAMOM is designed to represent fine-grained micro-dialectal variation

³<https://labelstud.io/>

⁴Available for review at this anonymized repository: <https://github.com/cardamom-paper/Cardamom-data>.

across *Egypt, Jordan, Lebanon, Mauritania, Palestine*, and *Saudi Arabia*. We use *micro-dialect* as an operational label for localized sub-country varieties that are recognizable to speakers and reflected in systematic differences in pronunciation, morphology, lexical choice, prosody, and grammatical patterns (Holes, 2004; Procházka, 2021). Capturing this level of variation is important for evaluating Arabic speech technologies beyond coarse country-level labels, which can mask substantial variation within the same national dialect category (Salameh et al., 2018; Abdul-Mageed et al., 2020).

Our taxonomy is informed by prior dialectological literature but is not intended to mechanically reproduce any single linguistic classification. Instead, it adapts established descriptions into categories suitable for computational speech evaluation, acknowledging that dialect boundaries are often gradual and shaped by regional, social, and historical contact. The labels therefore serve as operational annotation categories rather than a definitive linguistic classification; Appendix B discusses this distinction further, including a case where our own cited sources support finer subdivisions than the granularity we annotate.

Accordingly, CARDAMOM represents Egyptian speech through *Alexandrian, Cairene, Port Saidi*, and *Saidi* groups; Jordanian speech through *Madani, Falahi*, and *Badawi*; Lebanese speech through *Chamali, Jnoubi*, and *B'albaki*; Mauritanian *Hassāniyya* through *Western, Northern*, and *Southern/Eastern* groupings; Palestinian speech through *Madani urban, Northern Fallahi*, and *Southern Badawi*; and Saudi speech through broad regional categories including *Najdi, Hijazi, Eastern, Northern*, and *Southern*. These categories are not intended to exhaustively represent all local varieties within each country; rather, they define annotation units that are recognizable to native-speaker annotators, sufficiently frequent in publicly available speech, and useful for testing whether ASR systems generalize beyond broad country-level dialect labels. Appendix B provides a fuller discussion of the dialect classifications reported in the literature for the countries covered in CARDAMOM.

5.1 Phonological Motivation for Micro-Dialect Annotation

CARDAMOM captures several well-known axes of Arabic micro-dialectal variation, including reflexes of /q/, interdental preservation or merger, velar palatalization, and affrication of /dʒ/, each realized

Country	Micro-dialect	Segments	Total Hrs	Mean	CS Hrs	F/M
Egypt	Cairene	3,871	3.482	3.238	0.264	33.4/66.6
	Saidi	1,735	1.771	3.675	0.008	37.9/62.1
	Port Saidi	1,124	1.021	3.269	0.039	12.2/87.8
	Alexandrian	848	0.769	3.265	0.020	40.7/59.3
	TOTAL	7,364	6.889	3.368	0.327	32.1/67.9
Jordan	Falahi	3,276	4.540	4.989	0.119	18.6/81.4
	Badawi	2,899	3.968	4.928	0.005	26.6/73.4
	Madani	1,909	2.755	5.196	0.309	38.2/61.8
	TOTAL	7,729	10.806	5.033	0.407	26.5/73.5

Mauritania	Western	1,210	3.780	11.247	0.464	8.3/91.7
	Northern	1,205	3.809	11.380	0.470	8.1/91.9
	Southern	1,126	3.666	11.720	0.467	8.7/91.3
	TOTAL	1,314	3.998	10.953	0.473	7.7/92.3
Palestine	Falahi	1,564	2.720	6.260	0.028	9.0/91.0
	Badawi	864	1.461	6.088	0.001	3.1/96.9
	Madani	537	0.997	6.686	0.001	32.3/67.7
	TOTAL	2,956	5.159	6.283	0.031	11.5/88.5
Saudi Arabia	Southern	1,423	2.550	6.452	0.088	40.5/59.5
	Hijazi	1,413	2.661	6.779	0.250	95.0/5.0
	Najdi	1,089	2.234	7.384	0.156	3.4/96.6
	Eastern	956	2.023	7.618	0.044	17.9/82.1
	Northern	514	1.009	7.064	0.003	0.4/99.6
	TOTAL	5,376	10.425	6.981	0.538	39.6/60.4

Table 1: CARDAMOM statistics by country and micro-dialect. *Total Hrs* gives speech duration; *Mean* is average segment duration in seconds; *CS Hrs* gives code-switched speech duration; *F/M* reports the perceived speaker-gender split (some micro-dialects show extreme splits tied to source scarcity, e.g., Saudi Hijazi 95/5 and Saudi Northern 0.4/99.6; see *Gender distribution bias* in Limitations). Country-level totals (**bold**) count each segment once; per-dialect rows count label memberships and can exceed the total when segments carry multiple micro-dialect labels, most visibly for Mauritania (Table 5). An extended version with segment-duration range, transcript length, vocabulary, and speaking-rate statistics is in Table 4 (Appendix C).

differently across the Egyptian, Jordanian, Palestinian, Saudi, Lebanese, and Mauritanian varieties in the corpus (e.g., MSA قلب *qalb* “heart” surfaces as *ألب* *ʔalb* in Cairene, *كلب* *kalb* in Palestinian North Rural, and *گلب* *galb* in Hassaniya). These patterns motivate fine-grained annotation beyond country-level dialect labels; Table 3 (Appendix B) gives the full set of phoneme-by-phoneme correspondences with lexical examples and citations.

6 Corpus Statistics and Analysis

6.1 Micro-dialect and Transcript Statistics

Table 1 reports corpus statistics by country and micro-dialect, including the number of segment, total speech duration, mean segment duration, code-switching (CS) hours, perceived gender distribution, average transcript length (AVT), vocabulary size, and speaking-rate estimates. The corpus comprises 27,420 segments totaling ~40 hours. While some varieties, such as Egyptian Cairene and Jor-

danian dialects, are well represented, others, such as Lebanese B'albaki and Saudi Northern, are less represented but add unique linguistic diversity.

Average utterance duration varies notably across dialects, with Egyptian micro-dialects having shorter segments and Mauritanian the longest; Lebanese varieties fall in a mid-to-upper range (6.7–10.3 seconds). CS prevalence is unevenly distributed across micro-dialects, with Mauritanian, Jordanian Madani, Lebanese, and Egyptian varieties contributing the largest amounts, while Palestinian, Saudi, and Jordanian Bedouin subsets contain very little CS speech. Appendix G provides representative CS examples. Similarly, gender distributions are highly micro-dialect dependent, with some subsets being female-skewed and others male-skewed.

A similar pattern is observed in the transcript's length and lexical diversity (Table 4, Appendix C). Lebanese and Mauritanian subsets exhibit the longest transcripts and some of the highest vocabulary rates. Using words-per-second (WPS) and characters-per-second (CPS) as coarse proxies for speaking rate, the Egyptian and some Saudi dialects exhibit the fastest speech, while Palestinian and Lebanese are comparatively slower, consistent with prior findings (Talafha et al., 2024). The above findings are influenced by the domain of the underlying YouTube sources (e.g., interviews vs. vlogs, topic, recording conditions, and conversational formality) and by the segmentation strategy.⁵

6.2 Quantitative Micro-dialectal Overlap

To complement the aggregate corpus statistics, we examine the frequency and composition of multi-label assignments. These assignments identify utterances that annotators judged compatible with more than one micro-dialect and therefore provide a corpus-level view of where the operational label boundaries overlap.

The extent of co-assignment varies substantially across the sampled regions. As shown in Table 5 (Appendix C), Mauritania has the largest pairwise overlap counts, with extensive co-assignment among the three Hassaniya-oriented regional labels. This pattern should be interpreted with caution. Because micro-dialect-specific Mauritanian material

was difficult to obtain, much of the available data represents mainstream or broadly shared Hassaniya speech rather than clearly localized varieties. Annotators therefore judged many Mauritanian segments compatible with multiple regional labels.

Outside Mauritania, Jordan has the largest overlap counts: Badawi–Falahi and Falahi–Madani occur in 178 and 171 multi-label segments, respectively, compared with 23 for Badawi–Madani. Within this corpus, this pattern is consistent with Falahi sharing features with both the Badawi and Madani categories, although it does not by itself establish Falahi as an intermediate linguistic variety. In Egypt, co-assignment is concentrated around Cairene, which shares substantial overlap with the coastal varieties Alexandrian (130) and Port Saidi (67), whereas overlap involving Saidi and between other pairs of regional varieties is sparse (2–10). Saudi Arabia shows much less co-assignment, with most observed intersections containing only a few segments (e.g., one Eastern–Southern segment). These low counts indicate that the corresponding labels were rarely co-assigned in this corpus; they should not be taken as direct evidence of categorical linguistic separation.

Table 9 illustrates the kinds of utterances receiving multiple labels across countries with different overlap profiles. In Jordan, *يلا بخاطرك* (alright, see you!') (Badawi, Falahi) and *اه والله مربوط* (yes, that is correct') (Falahi, Madani) contain widely shared lexical items and discourse expressions that provide limited evidence for assignment to a single variety. Similarly, the Egyptian examples *استنى يابا* (wait, Dad') (Alexandrian, Port Saidi) and *فلوس باباكي متلزمناش* ('we don't need your father's money') (Alexandrian, Cairene) illustrate how common everyday expressions may be compatible with multiple neighboring varieties. In Saudi Arabia, where co-assignment is less frequent, *تماما ينطبق نفس الشيء على الرجال* ('exactly, the same thing applies to men') (Hijazi, Najdi) illustrates how relatively formal or broadly shared phrasing may provide few variety-specific cues. Overall, the examples suggest that multi-label assignments can arise from shared lexical and discourse material, limited variety-specific evidence within short utterances, and genuine overlap among localized varieties. Their distribution should therefore be understood as a property of both the sampled speech and the annotation framework.

Finally, the observed co-assignment counts may be influenced by source domain, topic, and variation in annotation practices. Although

⁵For example, podcast-style recordings often contain longer, more monologic turns than daily conversations. Thus, differences in duration, code-switching prevalence, lexical statistics, and speech-rate metrics may partially reflect source-domain composition rather than linguistic variation.

Table 2: WER and CER, in %, per model across countries and micro-dialects (test set). *Cnt*: Country, *M-Dia*: Micro-dialect, *O-*: Omni, *Sea-v2*: Seamless-v2, and *W-v3*: Whisper-v3. Best result per dialect is in **bold**. Per-dialect test-set sizes are listed in Table 11 (Appendix H); Table 14 (Appendix J) reports 95% bootstrap confidence intervals for WER per micro-dialect.

multi-label annotation was permitted, annotators may have differed in how readily they applied multiple labels; this possibility is particularly relevant when interpreting the low co-assignment counts in the Palestinian subset. In addition, since the corpus is drawn from YouTube, the same speakers may occur across multiple segments. To assess whether the reported patterns are dominated by a small number of recurring speakers, Appendix D reports estimated speaker diversity based on automatic speaker-embedding clustering.

7 Zero-Shot Benchmarking

We evaluate CARDAMOM primarily in a zero-shot ASR setting, then show that its train/development split supports adaptation (Section 7.2) and that the micro-dialect labels support identification as a downstream task (Section 7.3), and analyze transcript-level dialectness to contextualize ASR performance. We split the corpus into train, development, and test sets in a micro-dialect-wise manner; details are in Appendix H.

7.1 Automatic Speech Recognition (ASR)

We evaluate zero-shot ASR on the test and validation splits using four recent multilingual speech recognition systems, without fine-tuning on CARDAMOM. Performance is reported with word error

rate (WER) and character error rate (CER), after applying the same text-normalization pipeline to all systems (Appendix I); because dialectal Arabic lacks standardized orthography, these values reflect both acoustic recognition errors and residual orthographic mismatch after normalization. For each micro-dialect, we evaluate all test segments annotated with that label, including segments that overlap with other micro-dialects. MSA-only clips are excluded.

Models. WHISPER-V3, a large multilingual encoder-decoder model, is a strong Arabic ASR baseline (Radford et al., 2023). SEAMLESS-V2 is a multilingual speech model supporting transcription and translation (Barrault et al., 2023). OMNIASR-LLM-7B-V2 and OMNIASR-CTC-7B-V2 are omnilingual ASR models differing in decoding strategy, generative LLM-based versus CTC-based (Keren et al., 2025). Table 2 reports WER and CER by country and micro-dialect. Overall, OMNIASR-LLM-7B-V2 is the strongest system, obtaining the best WER for 20 of 21 micro-dialects and the best CER for 17 of 21, with especially clear gains for Jordanian dialects (WER 28.9–33.6) and Saudi Eastern, Najdi, and Southern. The only WER exception is Lebanese B'albaki, where Whisper-v3 is best (62.2), though OmniASR-LLM remains competitive.

Results vary substantially across regions: Jordanian micro-dialects are easiest overall; Egyptian and Palestinian dialects fall in a middle range, with errors remaining high for Port Said, Saidi, and Palestinian varieties; and Lebanese and Mauritanian dialects are considerably more challenging. In Lebanon, all models struggle on B'albaki, while OmniASR-LLM is much stronger on Chamali and Jnoubi. Mauritanian varieties are hardest overall (best model still ~76 WER, 48–49 CER), suggesting a major mismatch with the pretraining data distribution. Within most countries, the mainstream capital-associated variety yields the lowest WER (e.g., Cairene, Madani), suggesting that capital and media-centered dialects are better represented in web-scale pretraining data and ‘peripheral’ varieties are correspondingly under-represented. Saudi Arabia is the exception: despite Najdi being mainstream, Eastern yields the lowest WER, likely due to proximity to the broader Gulf variety.

7.2 Adaptation

The zero-shot results above use CARDAMOM purely as an evaluation resource. To demonstrate the intended use of its train/development/test partitions and give a more cautious, uncertainty-aware picture of the per-dialect comparisons in Table 2, we additionally fine-tune all four systems on the CARDAMOM training split (Appendix J reports checkpoints, hyperparameters, and compute). Whisper-v3 and Seamless-v2 are adapted with LoRA on the query/value projections; both OMNIASR variants are fully fine-tuned. Validation uses the development split; the test split is never used during adaptation. We report 95% confidence intervals from 2,000 bootstrap resamples over the test set, including for the smallest Lebanese subsets (B’albaki: 81, Chamali: 362, Jnoubi: 478 test utterances), capturing test-sample uncertainty rather than training-seed variance, since each adapted model was trained once.

Table 12 (Appendix J) compares aggregate WER/CER under the zero-shot and adapted settings. Adaptation reduces both error rates for Whisper-v3 and the two OMNIASR variants. The adapted OMNIASR-LLM model achieves the lowest overall WER and CER, reaching 35.21% WER and 16.04% CER, compared with 43.47% and 20.67%, respectively in the zero-shot setting. For Seamless-v2, adaptation yields only a small reduction in WER (53.13% to 52.48%), although its CER decreases more clearly (28.84% to 25.38%). Appendix J reports the full per-micro-dialect breakdown with confidence intervals for both settings. The overall pattern of relative difficulty across micro-dialects remains qualitatively similar after adaptation, but differences involving small test subsets, such as Lebanese B’albaki and Saudi Northern, should not be interpreted as conclusive.

7.3 Micro-Dialect Identification

The micro-dialect labels in CARDAMOM are not only used to stratify ASR error rates (Table 2); they also directly support micro-dialect identification (MDI) as a downstream task. We define three audio-based identification tasks over the same splits (Appendix H): (i) *country identification* (6-way), (ii) *global micro-dialect identification* (21-way), and (iii) *country-conditioned micro-dialect identification* (given the gold country). We benchmark zero-shot prompting of QWEN3-OMNI versus the same model after multitask LoRA fine-tuning, and a ded-

icated WHISPER-LARGE-V3-based classifier with a shared encoder and three jointly trained heads (task and training details in Appendix K).

Table 16 (Appendix K) reports the full results. Zero-shot QWEN3-OMNI performs far above chance but is insufficient for fine-grained identification (19.20% accuracy on the 21-way task). LoRA fine-tuning yields large, significant gains across all three tasks (e.g., +58.46 points on global micro-dialect identification, 95% CI [57.32, 59.59]), and hierarchical consistency between independently predicted country and micro-dialect labels rises from 33.67% to 95.48%. The dedicated Whisper classifier further outperforms fine-tuned Qwen3-Omni (e.g., by 7.91 points on global micro-dialect identification, 95% CI [7.07, 8.76]), reaching 95.67% country, 85.57% global micro-dialect, and 88.20% country-conditioned accuracy.

7.4 Dialectness Analysis

To assess how strongly the transcriptions exhibit dialectal characteristics rather than MSA, we score each segment with the ALDi model (Keleg et al., 2023) and treat dialectness (ALDi score) and recognition difficulty (ASR error rate) as separate axes. MSA-only segments score lowest (8.5%) and multi-label intersections highest (up to 97.1%), confirming a strong dialectal signal in the transcripts; critically, dialectness alone does not explain ASR difficulty, as capital-associated varieties such as Jordan-Madani and Egypt-Cairene remain comparatively easy to recognize despite scoring highly on dialectness. Appendix L reports the full per-micro-dialect breakdown and Figure 3.

8 Conclusion

We introduced CARDAMOM, a micro-dialectal Arabic speech corpus covering 21 localized varieties across Egypt, Jordan, Lebanon, Mauritania, Palestine, and Saudi Arabia. With ~40 hours of community-curated, transcribed YouTube speech and rich speaker-level metadata, CARDAMOM enables fine-grained ASR evaluation beyond coarse country-level dialect labels. Zero-shot benchmarking of four SOTA multilingual ASR systems confirms that micro-dialectal variation poses uneven challenges, with Mauritanian and Lebanese varieties hardest and OMNIASR-LLM the strongest baseline overall; adapting these systems on CARDAMOM’s training split narrows, but does not close, these gaps. We further show that CARDAMOM’s

micro-dialect labels are directly learnable as a downstream identification task, well above zero-shot and chance performance, supporting their use as a primary evaluation target rather than only as metadata for organizing ASR error breakdowns. In future work, we plan to expand CARDAMOM to additional Arabic countries and micro-dialects, and to enrich the annotation with phoneme transcriptions, emotion labels, and translation.

Limitations

Incomplete micro-dialect coverage. Although CARDAMOM spans 21 micro-dialects across six countries, the coverage within each country is uneven. Several micro-dialects, such as Lebanese B’albaki and Saudi Northern, contain substantially fewer segments than their better-represented counterparts (Table 2). This imbalance reflects the limited availability of suitable public speech material for certain localized varieties rather than an editorial choice, and it constrains the conclusions that can be drawn about these subsets. We mitigate this limitation by reporting results at the micro-dialect level, documenting the size of each subset, and interpreting low-resource varieties as diagnostic evaluation cases rather than as balanced training partitions. More broadly, CARDAMOM does not cover all Arabic-speaking countries or all sub-national varieties within the six countries it includes; dialects from the Maghreb, Gulf, or Nile Valley periphery, for instance, are absent. Future extensions should expand coverage to additional countries and underrepresented local varieties, prioritizing micro-dialects for which current ASR systems show high error rates or limited robustness.

Domain and genre effects. The corpus is drawn entirely from YouTube, and the distribution of genres, including podcasts, vlogs, interviews, old television serials, and informal conversations, is uneven across micro-dialects. As noted in Section 6, aggregate statistics such as average segment duration, code-switching prevalence, speaking rate, and lexical diversity are influenced by the domain composition of the underlying sources, not only by linguistic properties of the variety. We do not have a reliable way to retroactively assign a genre label (interview, vlog, podcast, broadcast, etc.) to each of the 27,420 segments, since annotators were free to pull from any non-scripted, naturally occurring content they could find for their variety, and many of these are casual personal videos

with no clean genre metadata attached at collection time; for several of our lowest-resource micro-dialects, suitable public speech was already scarce, so our priority during collection was finding any usable naturalistic speech for that variety at all, rather than sampling within specific genre categories. Our two content requirements were unscripted, non-read-out speech, to capture naturalistic dialectal usage, and segment-level audibility and transcribability, regardless of recording setting; we did not filter or track by recording environment (e.g., studio vs. phone-recorded), since intelligibility rather than production quality was our inclusion bar. CARDAMOM’s source material is naturalistic and unscripted by design, but genre and recording-condition distribution across the corpus is uncontrolled and unlabeled. We mitigate this limitation by reporting duration, code-switching, and speaking-rate statistics descriptively rather than treating them as definitive dialectal properties, and by interpreting cross-variety differences in light of possible source-domain effects. Future extensions should increase genre balance within each micro-dialect and include more controlled sampling across conversational settings, recording conditions, and registers.

Gender distribution bias. The perceived gender distribution in CARDAMOM varies substantially across micro-dialects and is highly skewed in some subsets (e.g., Saudi Hijazi is 95% female, while Saudi Northern is 99.6% male). These imbalances reflect the availability of suitable publicly accessible speech from each variety rather than a principled sampling strategy: for several of our lower-resource micro-dialects, publicly available YouTube content covering that specific variety was already scarce, which left little room to also balance for speaker gender within that subset, since annotators could only work with the videos that existed for a given variety rather than curate toward a target gender distribution. This is a known pattern in YouTube-sourced dialectal speech corpora more broadly; Casablanca (Talafha et al., 2024), for instance, reports similarly skewed gender distributions across some of its dialects for the same underlying reason. We mitigate this limitation by reporting gender distributions explicitly next to the corpus statistics (Table 1) and by treating gender metadata as suitable for aggregate descriptive analysis rather than balanced subgroup comparison within every micro-dialect. Model evaluations

stratified by gender should therefore account for the underlying data skew, and future extensions should target more balanced speaker coverage where suitable public speech is available.

Linguistic proximity across borders. Some micro-dialects that straddle national boundaries share strong phonological and lexical features, making their boundaries difficult to distinguish computationally and even perceptually. For example, Jordanian Badawi and Saudi Northern both exhibit Bedouin-type features, including the realization of /q/ as [g] and conservative vowel systems, that are more similar to each other than to the urban varieties of their respective countries. We mitigate this issue by treating such cases as expected boundary phenomena rather than annotation failures, and by using multi-label annotation where an utterance plausibly belongs to more than one local variety.

Orthographic inconsistency. Arabic dialects lack a standardized writing system, and transcription conventions vary across annotators, regions, and even within the same speech community. A single spoken form may therefore have multiple valid written realizations; for example, شفتو and شفته ('I saw him') are both attested across Egyptian varieties. We mitigate this limitation by providing annotators with shared transcription guidelines and by applying the same normalization pipeline across all ASR systems before computing WER and CER. Nevertheless, residual orthographic variation is unavoidable and may inflate error rates beyond purely acoustic recognition errors. This is a known challenge for dialectal Arabic ASR evaluation and further motivates future work with multi-reference evaluation metrics (Ali et al., 2015).

Annotation agreement. Because the corpus was collected through community-based annotation in which annotators primarily worked on varieties they know well, most segments were not independently labeled by multiple annotators. We therefore do not report inter-annotator agreement for the full corpus. Future extensions should include targeted double annotation for selected micro-dialect pairs, especially those with high linguistic proximity, to quantify boundary uncertainty more directly.

Source availability over time. As with any YouTube-sourced corpus, some source videos may become unavailable or be removed over time, whether by the uploader, by YouTube, or through our own takedown process. This is a known

and unavoidable property of building speech resources from public video platforms, and it affects prior work in the same space, including the MGB Challenge series (Ali et al., 2017, 2019), GigaSpeech (Chen et al., 2021), VoxLingua107 (Valk and Alumäe, 2021), Casablanca (Talafta et al., 2024), and AV-Speech (Ephrat et al., 2018). Because we release CARDAMOM as standoff annotations tied to source video IDs (Ethics and Data Statement), a share of the corpus may become unreconstructable for later users as source videos disappear; we mitigate this by releasing the dataset as early as possible and by not depending on any single mirror of the source material.

Data scale. With approximately 40 hours of transcribed speech, CARDAMOM is designed as an evaluation and adaptation resource rather than a large-scale training corpus. Training a full end-to-end ASR model from scratch on CARDAMOM alone would not usually be feasible, as modern large-scale speech models require orders of magnitude more data. The intended use cases are zero-shot and few-shot evaluation, fine-tuning or adapter-based adaptation of existing multilingual models, and micro-dialect identification; Sections 7.2 and 7.3 report adaptation and micro-dialect identification results that make this intended use concrete. We therefore view CARDAMOM primarily as a low-resource diagnostic benchmark for micro-dialectal robustness rather than a training-scale ASR corpus.

Ethics and Data Statement

CARDAMOM is constructed from publicly available YouTube videos containing public online speech and is intended for research on Arabic speech technology, especially ASR and micro-dialectal robustness. The dataset includes transcriptions, micro-dialect labels, code-switching labels, timestamps, source identifiers, and limited speaker-level metadata for aggregate analysis only. Gender labels are based on annotators' perception from the speech signal and should not be interpreted as speakers' self-identified gender or used for individual-level inference. Users should respect the terms of use of the original platforms and should not use the dataset for speaker identification, surveillance, biometric profiling, or inference of sensitive personal attributes.

Utterance-level, non-speaker-linked annotation. CARDAMOM does not contain any derived or aggregated speaker-level information, and we do

not perform any speaker-level analysis, including gender-based analysis. Perceived gender is annotated per utterance, exactly like the micro-dialect label, and is never linked across utterances to a speaker identity. Our labels describe properties of an utterance (what dialect is spoken in it, what the perceived speaker sounds like in terms of gender), not properties of a person or their location: a micro-dialect label reflects the variety spoken in a given utterance, not where the speaker currently lives, was born, or can be found. A speaker of Jordanian Badawi, for instance, may live anywhere, and our annotation makes no claim otherwise. This distinction is intended to head off any reading of CARDAMOM as enabling speaker-level geographic inference.

Release format and license. We release CARDAMOM as standoff annotations rather than re-distributed audio. For each utterance, we release the source YouTube video ID together with our own human-produced annotations, transcription, micro-dialect label(s), perceived gender, code-switching status, and start/end timestamps, along with code to reconstruct the corpus by fetching the corresponding audio segments from the original YouTube IDs. We do not redistribute audio, source video content, or any automatically generated transcription; every transcript and label released is our own human annotation. This follows the standoff-release approach used by other YouTube-sourced speech corpora, including the MGB Challenge series (Ali et al., 2017, 2019), GigaSpeech (Chen et al., 2021), VoxLingua107 (Valk and Alumäe, 2021), and Casablanca (Talafha et al., 2024). Public availability of the source videos is the basis for access during annotation; it does not by itself govern what we redistribute, and removal rights for any source video remain with the original uploader and with YouTube at all times. Cardamom’s released artifacts (transcripts, labels, timestamps, and reconstruction code) are made available for non-commercial research use; the annotations and guidelines are already available at <https://github.com/cardamom-paper/Cardamom-data> for review purposes.

A Related Work

Arabic Speech and ASR Resources. Arabic ASR research has historically relied on large broadcast and web-derived corpora. Early programs such as NIST EARS (Pallett, 2003) and DARPA GALE (Soltau et al., 2009) provided large-scale Arabic speech data, but were not designed around systematic fine-grained dialectal annotation. The MGB Challenge series (Ali et al., 2016, 2017, 2019) played a central role in Arabic ASR benchmarking: MGB-2 introduced a 1,200-hour Arabic multi-dialect broadcast recognition benchmark, MGB-3 shifted attention toward Egyptian Arabic YouTube speech in more realistic “in-the-wild” conditions, and MGB-5 expanded dialect identification to 17 Arabic-speaking countries while also targeting Moroccan Arabic speech recognition. QASR (Mubarak et al., 2021) later provided a 2,000-hour multi-dialect Al Jazeera speech corpus with lightly supervised transcriptions, segmentation, punctuation, and speaker information. More recent large-scale Arabic speech resources, such as MASC (Al-Fetyani et al., 2023), Aswat (Alkanhal et al., 2023), and SADA (Alharbi et al., 2024), further increased the amount and diversity of Arabic speech available for ASR training and evaluation. These resources substantially advanced Arabic ASR, but they were

primarily designed for broadcast, web, or country-level dialect settings rather than fine-grained micro-dialectal modeling.

Dialectal and Multidialectal Arabic ASR.

Recent work has increasingly emphasized dialectal coverage and multidialectal supervision. Casablanca (Talafha et al., 2024) is especially relevant, as it introduces a fully supervised multidialectal Arabic speech dataset covering eight Arabic dialects and provides annotations for transcription, dialect, gender, and code-switching. NADI 2025 (Talafha et al., 2025) further establishes spoken Arabic dialect processing as a shared-task setting, with subtasks for spoken dialect identification, multidialectal ASR, and diacritic restoration. ADI-20 (Elleuch et al., 2025) extends spoken Arabic dialect identification to 19 Arabic dialects in addition to MSA, providing large-scale supervision for dialect classification. Smaller but more focused resources, such as TuniFra (Choux et al., 2025), also highlight the growing need for carefully transcribed speech corpora targeting individual low-resource Arabic varieties. Together, these works show that the field is moving toward dialect-aware Arabic speech processing; however, most existing resources still operate at broad dialectal, regional, or country-level granularity.

Fine-Grained Dialect and Micro-Dialect Modeling.

The motivation for micro-dialectal Arabic speech resources is further supported by prior work in Arabic dialect identification. Text-based studies have shown that Arabic dialect variation can be modeled at a much finer level than national dialect categories. (Abdul-Mageed et al., 2018) introduced a city-level dataset of Arabic dialects, demonstrating that locality-level variation is computationally meaningful. Later work proposed Micro-Dialect Identification (MDI) in diglossic and code-switched environments (Abdul-Mageed et al., 2020), further showing that fine-grained Arabic dialect modeling is an important problem in Arabic NLP. In speech, however, this level of granularity remains underrepresented. Existing spoken resources such as MGB-5 (Ali et al., 2019), Casablanca (Talafha et al., 2024), NADI 2025 (Talafha et al., 2025), and ADI-20 (Elleuch et al., 2025) substantially improve dialectal coverage, but their labels are still primarily organized around countries or broad regional varieties rather than micro-dialects. This creates a gap between fine-grained dialect modeling in Arabic NLP and available supervision for Arabic ASR.

Code-Switching, Orthography, and Transcription Challenges. Arabic speech recognition is also complicated by code-switching, mixed orthographies, and the lack of standardized spelling conventions for dialectal Arabic. Code-switching corpora such as Mixat (Al Ali and Aldarmaki, 2024) and ZAEBUC-Spoken (Hamed et al., 2024) address bilingual Arabic-English speech, while Casablanca (Talafha et al., 2024) includes code-switching annotations within a multidialectal Arabic ASR resource. CAFE (Lachemat et al., 2025) further reflects the need to model spontaneous code-switching in North African Arabic contexts. These resources are important because dialectal Arabic ASR systems must often handle not only dialectal phonology and lexicon, but also English or French insertions, MSA alternation, and inconsistent orthographic choices. Evaluation work such as PolyWER (Kadaoui et al., 2024) shows that standard WER can be overly strict for code-switched speech, since valid transcriptions may differ by script, transliteration, or language-mixing convention. Similarly, work on Arabic ASR diacritization (Aldarmaki and Ghannam, 2023) highlights the importance of explicit transcription and evaluation choices in Arabic speech processing. These challenges motivate transcription guidelines that preserve spoken dialectal forms while making evaluation consistent across dialectal and code-switched segments.

Modeling and Benchmarking. Recent modeling work has focused on building Arabic ASR systems that are more robust to dialectal diversity. Large multilingual models such as Whisper (Radford et al., 2023), MMS (Pratap et al., 2024), and SeamlessM4T (SEAMLESS Communication Team, 2025) have become common baselines for multilingual and low-resource ASR. However, Arabic-specific studies show that these models still struggle under dialectal variation. (Talafha et al., 2023) benchmarked Whisper on diverse Arabic speech under zero-shot, few-shot, and full-shot settings, showing that performance degrades for unseen dialects. More recent work on Whisper fine-tuning for multidialectal Arabic ASR (Özyilmaz et al., 2025) explores dialect-specific and dialect-pooled adaptation strategies under data scarcity. Arabic-centered modeling efforts such as VoxArabica (Waheed et al., 2023) combine dialect identification with ASR, with Habibi introducing an open-source unified-dialectal Arabic TTS framework and benchmark built partly by repurposing ASR cor-

pora (Chen et al., 2026), while ArTST (Toyin et al., 2023) introduces an Arabic text-and-speech transformer for Arabic speech technology and ArVoice (Toyin et al., 2025) further reflect growing interest in Arabic speech modeling, although ArVoice targets MSA speech synthesis rather than dialectal ASR. Work on dialectal coverage and generalization (Djanibekov et al., 2025) further shows that robust Arabic ASR requires explicit coverage of MSA, dialectal speech, and code-switching, and that systems continue to struggle with data imbalance and unseen dialects. Evaluation has also become more systematic through the Open Universal Arabic ASR Leaderboard (Wang et al., 2025), which provides a common benchmark for open-source multidialectal Arabic ASR models.

Despite these advances, most Arabic speech resources still treat dialects as broad regional or national categories. This overlooks micro-level variation within the same country or macro-dialect, including localized differences in pronunciation, lexical choice, morphology, prosody, and code-switching behavior. CARDAMOM addresses this gap by introducing a micro-level multidialectal Arabic speech resource with 40 hours of transcribed speech and high-granularity labels for 21 micro-dialects. To the best of our knowledge, CARDAMOM is the first Arabic ASR resource designed explicitly around micro-dialect-level supervision across multiple localized Arabic varieties. By enabling evaluation of both within-dialect variation and cross-micro-dialect generalization, CARDAMOM complements existing broad-coverage resources by targeting a level of dialectal granularity that current Arabic ASR benchmarks do not capture.

B Micro-dialects Overview

B.1 Operational Status of the Taxonomy

The micro-dialect labels serve as operational annotation categories used to organize the dataset and structure evaluation, informed by prior dialectological literature and refined through the knowledge and judgments of native-speaker annotators. Our categorization is intended to reflect real-world linguistic communities as recognized by native speakers, so that the data represent the local varieties associated with these labels; although Table 3 and this appendix document clear linguistic differences among several of these micro-dialects, we do not claim that the proposed categories constitute

a definitive linguistic classification, since we have not conducted the kind of comprehensive linguistic analysis required to establish theoretical boundaries among these varieties or to characterize their precise status within broader levels of language variation. Linguists themselves do not always agree on a single correct granularity, and varieties we treat as single categories can be further subdivided: Jordanian Falahi is a clear example, as our own cited sources on Jordanian dialectology (Herin, 2010; Al-Wer and Herin, 2011; Herin and Al-Wer, 2013; Al-Wer et al., 2015) study individual localities such as Salt at a finer level than our three-way Madani-/Falahi/Badawi split, and other regional surveys further divide rural Jordanian speech into named town- or tribe-specific varieties (e.g., Salti, Bani Hassan, Karaki, Tafilawi) rather than treating it as one category. We chose a level of granularity that is recognizable to annotators, sufficiently attested in the speech we collected, and useful for evaluating ASR systems beyond country-level labels, while acknowledging that finer subdivisions remain possible and are supported by prior work.

B.2 Cross-Dialect Phonological Variation

Table 3 summarizes representative cross-variety phonological patterns referenced in §5.1 and throughout this appendix. Each row identifies an MSA phoneme by its IPA symbol and Arabic letter; the second column lists its attested realizations in specific Egyptian, Jordanian, Palestinian, Saudi, Lebanese, and Mauritanian varieties, with lexical examples illustrating the correspondence and arrows indicating the change from the MSA form to the variety-specific form.

B.3 Country and Micro-dialect Coverage

Arabic dialects exhibit substantial regional and social variation, and broad national labels often obscure the localized varieties that speakers use in everyday communication (Jarrar et al., 2023; Holes, 2004; Procházka, 2021; Zaidan and Callison-Burch, 2014). For this reason, CARDAMOM is designed to represent fine-grained micro-dialectal variation across *Egypt*, *Jordan*, *Lebanon*, *Mauritania*, *Palestine*, and *Saudi Arabia*. We use *micro-dialect* as an operational label for localized sub-country varieties that are recognizable to speakers and reflected in systematic differences in pronunciation, morphology, lexical choice, prosody, and grammatical patterns (Holes, 2004; Procházka, 2021). Capturing this level of variation is important for evaluating

MSA Phoneme	Variety-specific realizations & lexical example
Uvular Stop /q/ (ق)	EGY Cairene: realized as a glottal stop [ʔ] (e.g., قلب → ألب). JOR PAL Madani: commonly [ʔ] as well. EGY Saidi: shifts to [g]. PAL North Rural: shifts to [k] (e.g., كلب). PAL South Rural: shifts to the affricate [tʃ] (e.g., چلب). (Holes, 2004; Watson, 2002; Al-Wer and Herin, 2011; Youssef, 2021) LEB Chamali and Jnoubi (sedentary): collapse to [ʔ] (e.g., قلب → ألب). LEB B'albaki: retains [q] under a Bedouin substrate (e.g., قلب), with Zahle optionally aligning with the sedentary [ʔ]. (Ağbaht, 2023; Lentin, 2018) MAU Hassaniya: shifts to [q] represented by گ (e.g., قلب → گلب).
Interdental /θ/ (ث)	KSA Najdi and JOR Falahi: preserved as [θ]. KSA Hijazi and JOR PAL Madani: often merge to the alveolar stop [t] (e.g., ثلاثة → تلاثة). EGY Egyptian varieties: may merge to the sibilant [s] (e.g., ثم → سم). (Holes, 2004; Al-Wer, 2004; Youssef, 2021) LEB Chamali, Jnoubi, and Zahle B'albaki: merge to the alveolar stop [t] (e.g., ثلاثة → تلاثة). LEB Rural Akkari and Hermeli B'albaki: partial retention as [θ].
Interdental /ð/ (ذ)	KSA Northern and Southern KSA: preserved as [ð]. KSA Hijazi, EGY Cairene, and PAL Madani: shift to [d] (e.g., ذهب → دهب). PAL Falahi and Badawi: shifts to the emphatic [ðˤ] (e.g., هذا → هَذَا). (Holes, 2004; Al-Wer, 2004; Youssef, 2021) LEB merges to [d] (e.g., هذا → هاد, with هيدا as the dominant demonstrative). LEB Hermeli B'albaki: optional retention as [ð].
Velar Stop /k/ (ك)	JOR Falahi and PAL North Rural: undergo palatalization to [tʃ] (e.g., كيف → تشيف [tʃi:f]). EGY Egyptian and JOR PAL Madani: typically retain [k]. (Dickins and Watson, 2001; Youssef, 2021) LEB All Lebanese micro-dialects: retain [k] uniformly, with no kashkasha-style affrication anywhere in the country (e.g., كذاب stays كذاب).
Palato-alveolar /dʒ/ (ج)	EGY Cairene and Port-Saidi: de-affricate to a voiced velar stop [g] (e.g., جميل [gami:l]). EGY Saidi: can shift to an alveolar stop [d] in specific lexical environments (e.g., الديش → الحيش). (Watson, 2002; Holes, 2004; Youssef, 2021) LEB Chamali, Jnoubi, and Zahle B'albaki: de-affricate to [ʒ] (e.g., جبل [ʒabal]). LEB Rural Akkari and Hermeli B'albaki: variably retain [dʒ]. (Lentin, 2018) MAU Sharg: shifts to [ʃ] in المشتع → المجتمع.
Emphatic Coronal /tˤ/ (ط)	Emphasis/pharyngealization is typically retained as [tˤ]; in EGY Saidi, it may lose emphasis to [t] (e.g., طار → [ta:r]). (Watson, 2002; Davis, 1995)

Table 3: Key cross-variety phonological variation across Egyptian, Jordanian, Palestinian, Saudi, Lebanese, and Mauritanian varieties compared to MSA.

Arabic speech technologies beyond coarse country-level labels, which can mask substantial variation within the same national dialect category (Salameh et al., 2018; Abdul-Mageed et al., 2020).

Our micro-dialect inventory is grounded in prior dialectological work, but it is not intended to reproduce any single taxonomy mechanically. Instead, we use existing descriptions as a linguistic foundation and adapt them into annotation categories that are practical for speech data collection, recogniz-

able to native-speaker annotators, and sufficiently consistent for computational modeling. This design choice reflects the fact that dialect boundaries are often gradual rather than discrete, and that speech communities may share features across regional, social, and national boundaries.

In Egypt, CARDAMOM represents three practical micro-dialect groups: *Cairene*, *Coastal (Alexandrian and Port Saidi)*, and *Saidi (Upper Egyptian)*. This grouping reflects Egypt’s regional diversity, where pronunciation, lexicon, rhythm, and expression vary across regions, even though Cairo Arabic is widely understood through media exposure (Fashwan and Alansary, 2025; Abdel-Massih et al., 1979; El-Tonsi, 1987; Gadalla, 2000). This grouping is also consistent with broader atlas-based descriptions of Egyptian dialect areas, including the Delta, Nile Valley, Upper Egypt, Western Oases, and Bedouin varieties (Woidich, 1996; Miller, 2005).

In Jordan, CARDAMOM follows the widely used distinction between *Madani*, *Falahi*, and *Badawi* varieties. These categories capture major points along Jordan’s urban, rural, and Bedouin dialect continuum, including the role of the Ammani urban koiné, sedentary rural dialects, and Bedouin speech varieties (Palva, 1984; Al-Wer et al., 2015; Al-Wer, 2007; Palva, 2008; Herin et al., 2022).

In Lebanon, CARDAMOM includes three practical micro-dialect groups: *Chamali (Northern)*, *Jnoubi (Southern)*, and *B’albaki (Bekaa/Baalbek)*. These categories reflect localized variations relevant to the collected speech data while remaining practical for native-speaker annotation and downstream modeling. They are grounded in prior descriptions of Lebanese Arabic, where regional speech differs across northern, southern, Bekaa, Beiruti, and Mount Lebanon areas, alongside a media-driven dominant Lebanese variety associated with Beirut and central Mount Lebanon (Haff et al., 2022; Lentin, 2018; Germanos, 2009; Stone, 2008). Chamali captures northern varieties such as Tripoli, Zgharta, and Akkar speech (Joukhadar, 2023; Ağbaht, 2023), while Jnoubi reflects southern coastal and inland varieties, and B’albaki represents the Bekaa/Baalbek-Hermel area (Haff et al., 2022; Lentin, 2018; Germanos, 2009).

In Mauritania, CARDAMOM adopt three practical *Ḥassāniyya* micro-dialect groups: *Western (Gābla)*, *Northern (Sāhil)*, and *Southern/Eastern (Sharg)*. This grouping reflects Mauritania’s regional and sociolinguistic diversity, where

Ḥassāniyya is the dominant spoken Arabic variety but coexists with Pulaar, Soninké, Wolof, Zenaga, French, and other languages across different regions and urban settings (Naciri-Azzouz, 2023; Taine-Cheikh, 2020, 2018). As with the other countries, the goal is not to impose a rigid taxonomy, but to define annotation categories that preserve salient localized variation in the available speech data, especially differences in pronunciation, lexicon, and usage patterns (Francis and Hanchey, 1979; Hanchey and Francis, 1979; Taine-Cheikh, 2007).

In Palestine, we adopt a three-way classification consisting of *Madani urban*, *Northern Fallahi*, and *Southern Badawi* speech. This structure avoids reducing Palestinian Arabic to a simple city–village contrast and instead captures broader bundles of phonological, lexical, and grammatical features associated with urban, northern rural, and southern rural or Bedouin-adjacent varieties (Haff et al., 2022; Ulbah and Mohammed, 2024; Al-Wer and Herin, 2011).

In Saudi Arabia, CARDAMOM covers major regional dialect groups, including *Najdi*, *Hijazi*, *Eastern*, *Northern*, and *Southern* varieties. These categories reflect broad divisions commonly used in sociolinguistic and phonetic research and capture variation across central, western, eastern, northern, and southern Saudi speech communities (Ingham, 1994; Prochazka, 1988; Sambas, 2016; Asiri, 2009; Alqahtani, 2015; Sandouka and Alotaibi, 2021). Given the size and internal diversity of Saudi Arabia, these labels should be understood as high-level micro-dialectal groupings rather than exhaustive representations of all local speech varieties.

Our final inventory is grounded in this prior work, but adapted to the practical requirements of dataset curation: the categories must be meaningful to native speaker annotators, applicable to naturally occurring speech, and useful for evaluating model behavior beyond country-level labels. This allows CARDAMOM to preserve fine-grained regional and social variation that would otherwise collapse under broad national dialect categories.

B.4 Phonological Variation in Arabic: A Micro-Dialectal Analysis

Spoken Arabic is characterized by a high degree of phonological variation (Watson, 2002; Khan et al., 2011). An analysis of phonetic data across various micro-dialects reveals systematic axes of phonological divergence from MSA. The primary differ-

ences can be observed as follows:

The Reflexes of the Uvular Stop /q/ (ق). The voiceless uvular stop /q/ is one of the most salient sociolinguistic variables in Arabic dialectology (Watson, 2002; Holes, 2004). The data show a shift from /q/ to a glottal stop [ʔ] in *Cairene* and *Port-Saidi*, as well as in the *Madani* dialects of both Jordan and Palestine. In these micro-dialects, MSA /qalb/ (قلب, ‘heart’) is realized as [ʔalb] (ألب). Alexandrian shows a mixed pattern in the reported examples, retaining /q/ in قلب while showing glottalization in تقبل → تأبل. Other micro-dialects exhibit different reflexes. *Saidi* realizes قلب as [galb] (جلب), while the Mauritanian Hassaniya varieties realize qaf with a voiced velar stop reflex, represented orthographically as گ, as in قلب → گب. In the Palestinian data, North Rural *Falahi* shifts /q/ to [k] (كب), while South Rural *Badawi* shifts it to the affricate [tʃ] (چلب) (Al-Wer and Herin, 2011; Youssef, 2021). The Jordanian *Falahi* and *Badawi* micro-dialects retain qaf in the reported examples (Al-Wer, 2003). Lebanese *Chamali* and *Jnoubi* show glottalization, while *B’albaki* varies between retention and glottalization (Ağbaht, 2023; Lentin, 2018).

Interdental Fricatives /θ/ (ث), /ð/ (ذ), and /ðʕ/ (ظ). MSA maintains the interdental fricatives, a feature that is preserved in some micro-dialects but merged with stops, sibilants, or other reflexes in others (Watson, 2002; Al-Essa, 2022; Al-Wer, 2004). The interdental articulation is retained in the *Southern*, *Northern*, *Najdi*, and *Eastern* dialects of Saudi Arabia, as well as in the *Falahi* and *Badawi* dialects of Jordan and the North Rural *Falahi* and South Rural *Badawi* dialects of Palestine. For example, MSA /θala:Ta/ (ثلاثة, ‘three’) and /ha:ða/ (هذا, ‘this’) remain relatively unchanged in these varieties. Hassaniya also preserves interdental contrasts in many forms, although regional and lexical variation is attested (Taine-Cheikh, 2018, 2007).

In contrast, interdentals merge with alveolar stops or alveolar sibilants in *Cairene*, *Port-Saidi*, *Alexandrian*, *Saidi*, *Hijazi*, and the *Madani* dialects of Jordan and Palestine. For instance, /ð/ merges with [d] in *Hijazi*, *Cairene*, and *Madani* varieties, as in ذهب → دهب, while /θ/ merges with the sibilant [s] in the Egyptian varieties, as in ثم → سم. In *Hijazi* and the *Madani* dialects of Jordan and Palestine, /θ/ commonly shifts to [t], as in ثلاثة → تلاثة. In Lebanese *Chamali* and *Jnoubi*, /θ/ and /ð/ also show stop or sibilant reflexes, while *B’albaki* shows more variable retention and merger (Lentin, 2018).

Velar Palatalization. Another distinguishing feature in Arabic dialectology is the conditional palatalization of the voiceless velar stop /k/ (ك) to the palato-alveolar affricate [tʃ], a process often referred to in traditional Arabic philology as kashkasha (Cantineau; Holes, 2004; Dickins and Watson, 2001). This shift is active in the Jordanian *Falahi* and *Badawi* micro-dialects, as well as the Palestinian North Rural *Falahi* and South Rural *Badawi* micro-dialects. In these varieties, MSA /kajfa/ (كيف, ‘how’) is realized as [tʃi:f] (تشيف). In the Palestinian data, كذاب becomes تشذاب in North Rural *Falahi*, while South Rural *Badawi* retains كذاب. This indicates that palatalization is micro-dialect-specific and may also be lexically conditioned. This contrasts with *Cairene*, *Port-Saidi*, *Alexandrian*, *Saidi*, Lebanese varieties, and the *Madani* dialects of Jordan and Palestine, which retain [k] in the corresponding examples.

The Mauritanian Hassaniya varieties add further patterns not captured in the earlier four-country comparison. Besides the realization of /q/ as [g], they show variation involving غ /ghayn/ ڧh/, as in لغة → لفة in the Northern variety and صقير → صغير in Northern and Southern/Eastern. The same examples show de-emphasis of /sʕ/ to /s/, as in صغير → صغير. Additional examples include initial hamza reduction (نول → الأول) and a Western/Gabla emphatic reflex in اطراب → التراب. These patterns are consistent with descriptions of Hassaniya as a regional continuum with both shared and localized phonological features (Taine-Cheikh, 2018, 2020; Francis and Hanchey, 1979). Mapping the specific micro-dialectal data against MSA highlights distinct, systematic phonological rules. Whether through the lenition of /q/, the treatment of interdentals, or the presence of velar palatalization, each micro-dialect demonstrates a unique phonological profile that diverges from standard phonetic boundaries.

B.5 Egyptian Micro Dialects

Egyptian dialects are characterized by substantial regional diversity, reflecting geography as well as social, cultural, and historical factors (including internal and external migrations). Pronunciation, lexicon, rhythm, and styles of expression vary across regions. Modern media (cinema and television) have contributed to the spread of a widely understood variety, but it has not erased local distinctions (Fashwan and Alansary, 2025; Gadalla, 2000). Within

Egypt, fine-grained (“micro”) dialect work is facilitated by the fact that the country’s dialect map is described as “relatively well established” due to the *Atlas of Egyptian Rural Arabic* (Woidich, 1996), while earlier linguistic descriptions disproportionately focused on Cairo Arabic and provided comparatively scarcer coverage of regional varieties (Serreli et al., 2019). Accordingly, microdialectal analysis in Egypt is best framed as (i) adopting the atlas-based geographic skeleton and (ii) grounding micro-variation in diagnostic isoglosses at multiple linguistic levels.

Following the atlas-based perspective, Egyptian Arabic can be organized by first distinguishing the dialects of the “true Bedouins,” described as groups who arrived relatively recently and live on Egypt’s margins (e.g., Sinai and the Western/Eastern deserts) and are not fully sedentarized (Miller, 2005). The atlas then divides the “rural dialects” (sedentary rural population) into three main geographic areas—*Nile Delta*, *Nile Valley*, and *Western Oases*—each with subgroups. In the *Nile Delta*, the subgroups include *Western Dialects* (WD 1, 2, 3, 4), *North-Eastern Dialects*, *Central Dialects*, and *North Eastern Dialects* (NED 1 and 2). In the *Nile Valley*, the atlas distinguishes *Middle Egypt dialects* (NME 1–2, SME) and *Upper Egypt dialects* (UE 1, 2, 3, 4). *Western Oases* dialects include four oasis varieties: *al-Bahariyya*, *al-Farafra*, *ad-Dakhla*, *al-Kharga*.

Across these regions, reported diagnostic differences include phonological and morphological isoglosses (Miller, 2005; Woidich, 1996). A widely used macro-isogloss pair is: Cairo / central Delta: /j/ → /g/ and /q/ → /ʔ/ (e.g., *gamal* ‘camel’ جمل, ?alb ‘heart’ ألب); versus Sinai Bedouin: /j/ → /dʒ/ or /ʒ/ and /q/ → /g/ (e.g., *dʒamal* جمل, *galb* جلب). Another diagnostic concerns the interdental /θ, ð/: Sinai Bedouin is described as retaining interdentals (e.g., θala:θa ‘three’ ثلاث, ðe:l ‘tail’ ذيل), whereas Central Delta merges them to /t/ and /d/ (e.g., tala:ta ثلاث, de:l ذيل). Gender distinctions in plural verbal agreement are reported as retained in some areas but lost/neutralized in others (e.g., Sinai retains masc./fem. plural contrast, whereas central Delta patterns are described as neutralizing it). Morphologically, a diagnostic reported for Qena and farther south, and also in Bahariyya and Farafra (Mohamed, 2024), is the “Western imperfect paradigm.” The atlas also points to internal microvariation within Upper Egypt (e.g., UE1 vs. UE2).

In our CARDAMOM construction from YouTube speech, we operationalize a complementary, data-driven grouping that aligns with common high-level regional labels while preserving micro-dialectal coverage in our sampling. For Egypt, we group the collected speech into three practical categories: *Cairene* (Cairo), *Coastal/Delta urban varieties* (including Alexandrian and Port Saidi speech), and *Saidi* (Upper Egyptian). This grouping is not intended to replace the more detailed atlas-based classifications of Egyptian Arabic, but rather to provide annotation categories that are recognizable to native speakers and suitable for computational modeling. Each category still exhibits internal variation shaped by city–village differences, regional history, and patterns of contact.

B.5.1 Cairene Micro-dialect

The Cairo dialect is widely used and prominent, corresponding to Cairo’s political, cultural, and media importance; cinema and television have helped popularize and increase comprehension of this dialect (Abdel-Massih et al., 1979; El-Tonsi, 1987; Gadalla, 2000). It is described as flexible and easy to understand, with a strong ability to absorb new vocabulary from local dialects and other languages, making it a common variety for communication among speakers from different regions.

B.5.2 Saidi Micro-dialect

Saidi Egyptian refers to dialects spoken in southern Egypt, particularly in Beni Suef and extending through Minya, Asyut, Sohag, Qena, to Aswan. A key characteristic is the realization of /ʒ/, which is variable in Minya but is described as consistently realized as ج in more southern variants (Woidich, 1996). Moving southward, vowel lengthening increases, the pronunciation of emphatic consonants strengthens, and speech patterns become slower and more stable (Mohamed Eida and Habash, 2025). Despite differences, these dialects share a common phonological framework and are described as showing internally structured regional variation rather than sharply bounded linguistic divisions: from Minya to Aswan, systematic phonological variation forms a geographic continuum.

B.5.3 Coastal Micro-dialects

Coastal dialects include those spoken in seashore cities such as Alexandria, Port Said, Damietta, and Marsa Matrouh (Woidich, 1996). They are characterized by historical and cultural influences associ-

ated with coastal cities' openness to trade and contact. The *Alexandrian micro-dialect* is described as differing from Cairene in rhythm and pronunciation and using local vocabulary related to sea life and trade; it is characterized by a fast rhythm and a relatively sharp tone with clear pronunciation (e.g., a tendency for ش and س to be pronounced clearly without softening) (Behnstedt and Woidich, 2018). The *Port Saidi micro-dialect* is described as softer in tone with a slightly slower rhythm, including slight elongation in some parts (especially in informal contexts), the use of specific local idioms, and effects from internal migrations reflecting the city's commercial character and history as an important port.

B.6 Jordanian Micro-dialects

Jordanian Arabic forms a continuum of mutually intelligible dialects across the Kingdom of Jordan, with an emerging common variety alongside significant regional and social sub-varieties that differ in phonological and morphological features (Palva, 1984; Al-Wer et al., 2015). Traditional accounts divide Jordan's vernaculars into *sedentary* vs. *Bedouin* types (Palva, 1984): sedentary varieties further split into rural (*Falāḥī* فلاحي) and urban (*Madani* مدني) dialects, while (*Badawī* بدوي) dialects are associated with nomadic or semi-nomadic tribal origins. In recent decades, strong dialect contact in urban centers, especially Amman, has also produced a mixed koiné that functions as a prestige urban variety (Al-Wer, 2007); below, we overview the three primary micro-dialect groups: Madani, Falahi, and Badawi.

B.6.1 Madani – Urban Koiné Dialect

The urban dialect of Amman, the capital and largest city, is often described as a new *koiné* that emerged from dialect mixing (Al-Wer, 2007; Al-Wer, Enam, 2002). Amman was a small town in the early 20th century, but its designation as the capital brought major migration from northern Jordan (e.g., Salt and Irbid), southern Jordan (Karak, Ma'an), Bedouin communities, and waves of Palestinian refugees after 1948 and 1967 (Al-Wer, 2007). As a result, Ammani speech formed as a hybrid combining features from these sources, with particularly strong influence from northern Jordan (Horani) input (Al-Wer, 2007; Palva, 2008). Over a few decades, these initially mixed inputs converged into a stable local variety by the third generation of native Ammani speakers (Al-Wer, 2007).

The modern urban Jordanian koiné (exemplified by Ammani speech) is characterized by reduction or leveling of some marked rural or Bedouin features. For example, northern Jordanian and rural dialects may affricate /k/ to [tʃ] before front vowels (e.g., /keef/ “how” → [tʃi:f]) (Herin, 2010; Herin and Al-Wer, 2013; Al-Hawamdeh, 2015). Although this feature was brought to Amman by early migrants (e.g., from Salt), it rapidly receded in the capital: first-generation Ammanis already shifted to [k] in all contexts (Al-Wer, 2007). In Amman, affrication became stigmatized as a rural marker, though it continues in cities such as Irbid and Ramtha, especially in semi-urban and rural-urban transitional communities (Herin and Al-Wer, 2013).

Another case of leveling concerns the second-person plural system. Traditional sedentary Jordanian (*Falāḥī* فلاحي) varieties distinguish masculine /-ku/ vs. feminine /-ken/ (e.g., laʕindku لعندكو vs. laʕindken لعندكن), and in the north /k/ may affricate, yielding forms such as laʕindtʃen لعندتشن (Herin and Al-Wer, 2013; Herin, 2014; Palva, 2008). In Amman, the urban koiné shows functional neutralization to a single plural form /-kum/ (e.g., laʕindkum لعندكم) for both genders in most contexts (Al-Wer, 2007).

Phonologically, urban Jordanian shares traits with other Levantine city dialects, including variation in the reflex of *qāf* (ق) between [ʔ] and [g]. Studies report that [ʔ] is favored by women while men more often use [g], and both variants are socially meaningful in Amman (Al-Wer and Herin, 2011; Abd-el Jawad, 1986): [ʔ] is associated with an urban or Palestinian-oriented identity, while [g] indexes a more “tribal” or East Bank identity, yielding stable sociolinguistic variation in (q).

Overall, the Madani koiné of Amman has become the prestigious urban variety of the capital and a key source of linguistic influence. At the same time, *Falāḥī* and *Badawī* dialects remain widespread and locally dominant elsewhere, and media usage varies by genre (MSA in news, colloquial in entertainment).

B.6.2 Falāḥī – Sedentary Rural Dialects

The term *Falāḥī* (“peasant” or rural) refers to the sedentary dialects spoken in Jordan's villages and smaller towns by non-nomadic communities. These rural dialects are part of the broader Southern Levantine Arabic continuum and share many features with Palestinian rural speech. In north-

ern and central Jordan (historically *Ḥawrān*, from Amman up to southern Syria), the local rural vernacular is often called the Horani dialect (*ḥōranī* حوراني) (Palva, 1984). Horani varieties are characterized by classic Levantine rural features, including /q/ realized as [g] (e.g., *qalb* → *galb*) and conditional palatalization (affrication) of /k/ to [tʃ] before front vowels (e.g., *kīf* → *chīf*) (Herin, 2010; Herin and Al-Wer, 2013; Al-Hawamdeh, 2015). These features are widespread in northwest Jordan (Irbid, Ajloun, Balqa) and are well documented, though they are often stigmatized, and younger rural speakers frequently adopt urbanized variants in casual speech (Al-Wer, 2007).

Beyond phonetics, *Falāḥī* dialects preserve older grammatical distinctions, including gender-specific forms in plural addresses and verb conjugations (Al-Wer, 2007), and they use the proclitic *b-* to mark present-tense verbs (e.g., *b-niktub* بـنكتب “we are writing”), unlike some Bedouin dialects that lack *b-* (Al-Wer and Herin, 2011). Lexically, rural Jordanian Arabic overlaps substantially with neighboring Palestinian dialects, alongside localized vocabulary tied to agriculture and village life. Sedentary dialects are not monolithic: there is notable sub-regional variation (e.g., far north vs. the Karak plateau), including regional realizations of the feminine ending “-a” (*tā’ marbūṭa*), raised to [e] in southern rural Jordan (*maktabe* مكتبي) and often realized as a more central [æ] in northern dialects (*maktabeh* مكتبة), in contrast to Bedouin [a] (Palva, 2008). Nevertheless, *Falāḥī* varieties remain mutually intelligible within the broader sedentary Levantine type, and many rural speakers are bidialectal, using the local dialect at home but shifting towards urban speech in formal settings or when interacting with outsiders.

B.6.3 Badawi – Bedouin Dialects

The Bedouin dialects of Jordan are associated with Bedouin tribes, traditionally pastoral nomads of the eastern deserts and southern steppe. Linguistically, they fall under Arabian Bedouin Arabic and are often classified as “Northwest Arabian” Arabic (Palva, 2008). In Palva’s classification, the Bedouin-type dialects spoken in Jordan (and neighboring desert regions of Syria and Arabia) form an eastern subgroup of Northwest Arabian dialects (Palva, 2008; Herin et al., 2022) and show strong affinities with the dialects of the Negev, Sinai, and the Najd rather than with sedentary Levantine city and village dialects (Palva, 2008; Herin

et al., 2022). Within Jordan, Bedouin varieties further differ along tribal lines and historical origins: southern Jordan dialects (e.g., *Ḥuwayṭāt*, Banī ’Aṭīyyah, the Bdul of Petra, and the ’Nmāt) share features with Sinai and Negev Bedouin (Palva, 2008), while major tribes in central and northern Jordan (e.g., Banī Ṣaxr, Banī Ḥasan, Sirḥān) speak North Arabian (Najdi)–type dialects associated with the ’Anaza and Shammār confederations (Herin et al., 2022). Some north-eastern Bedouin communities (e.g., Sirḥān of the Ḥamād) speak *šāwī* Arabic, similar to Syrian–Iraqi Bedouin dialects and often distinguished by plural verb forms ending in *-ūn* (e.g., *yīgūlūn* يـقولون “they say”) (Herin et al., 2022).

Despite local differences, Jordanian Bedouin dialects share defining features. Phonetically, /q/ is typically realized as [g ڭ] (e.g., *gabīl* for *qabīl* “before”), and /k/ generally remains [k ڤ] (with /k/-palatalization described as rare and largely limited to certain words or older speakers). They also tend to preserve classical vowel features reduced in sedentary speech; for instance, /aw/ and /ay/ may be retained as diphthongs or only partially monophthongized, whereas urban Jordanian often realizes them as [o:] and [e:] (Palva, 2008). Grammatically, Bedouin varieties often lack (or optionally use) the habitual *b-* prefix on present tense verbs, using forms such as *aktub* or an auxiliary (e.g., *gāʔid aktub* گاعد أكتب “I am writing”) (Al-Wer and Herin, 2011), and they preserve lexical items and idioms tied to desert life. Although many Bedouin groups have become settled and dialect contact has led to gradual convergence in some communities (Herin et al., 2022), core Bedouin features remain salient identity markers (e.g., [g] vs. [ʔ] for /q/), and many speakers are bidialectal, using Badawi at home and shifting to the urban koine in mixed settings.

B.7 Lebanese Micro-dialects

Lebanese micro-dialects vary around five provincial clusters and one media-driven dominant dialect (Haff et al., 2022; Lentin, 2018; Germanos, 2009). The *dominant Lebanese* is anchored around Beirut in central Mount Lebanon and was projected nationally and pan-Arab by the Rahbani musical theater, the Fairuz repertoire and the folkloric serials broadcast on the major Lebanese media and TVs from the 1960s onward (Stone, 2008) reproduced in formal and mediated contexts. *Beirutī* clusters around the historical city neighborhoods (Achrafieh, Basta, Ras Beirut) and behave as an urban prestige form

that absorbs migrant inputs and re-allocates them through contact-driven leveling (Germanos, 2009).

B.7.1 Northern

The *Northern* (Chamali) cluster runs from a brisk, Syrian-leaning Tripoli speech through the Maronite-marked Zgharta variety with its non-verbal negation patterns (2023), into the rural Akkar varieties (Ağbaht, 2023).

B.7.2 Southern

The *Southern* cluster splits between the coastal Sidon and Tyre varieties, which align with Palestinian coastal Arabic in vowel quality and selected morphology, and the inland Jizzine and Nabatieh villages, which retain more conservative traits (Haff et al., 2022). The *Bekaa* divides between the urban Zahle and the Baalbek-Hermel cluster of the northern valley, which carries a marked bedouin substrate. Eastern Bekaa shifts more southern dialects. The *Jabal* cluster covers the Mount Lebanon villages outside the Northern Matn belt, where conservative phonological reflexes (notably the realization of *qāf*) and Aramaic-substrate lexicon are best preserved (Lentin, 2018; Germanos, 2009).

Despite this microdialectal richness, computational coverage of Lebanese remains thin. The Lebanese-side portion of Curras+Baladi (Haff et al., 2022) is to date the only morphologically annotated Lebanese corpus, complemented on the Syrian side of the Levantine continuum by Nābra (Nayouf et al., 2023). CARDAMOM's explicit microdialectal split for Lebanese and coverage of its Southern, Chamali and Bikaa variants is meant to help close this gap.

B.8 Mauritanian Micro-dialects

Ḥassāniyya Arabic, also known as Mauritanian Arabic or *klām Ḥassān*, is the dominant spoken Arabic variety in Mauritania and the mother tongue of the Biḍān and Ḥarāṭīn. It also extends beyond Mauritania into the wider western Sahara. Mauritania itself is a multilingual and multiethnic country, where *Ḥassāniyya* coexists with Pulaar, Soninké, Wolof, Zenaga, French, and other languages, and where linguistic practices vary by region, neighborhood, social class, age, and urban setting (Naciri-Azzouz, 2023). Historically, *Ḥassāniyya* is associated with the Banū Ḥassān Arab tribes and is generally classified as a Bedouin or Hilālīan-type Arabic variety. Its development in the western Sahara has also been shaped by prolonged contact with

Zenaga Berber and, in southern areas, with West African languages such as *Pulaar*, *Soninké*, and *Wolof*, which helps explain why it differs substantially from both MSA and many mainstream North African Arabic varieties (Taine-Cheikh, 2020).

For Mauritania specifically, the literature supports treating *Ḥassāniyya* as a regional and sociolinguistic continuum rather than a single homogeneous dialect (Francis and Hanchey, 1979; Cohen and Chennafi, 1963; Taine-Cheikh, 2020; Heath, 2004). This is consistent with descriptions of Mauritania as a highly diverse linguistic space: the north tends toward a Ḥassānophone majority, while multilingualism is more common in the south and the Senegal River Valley; large cities such as Nouakchott are especially heterogeneous, with *Ḥassāniyya*, Pulaar, Wolof, French, and other languages functioning differently across contexts (Naciri-Azzouz, 2023). Pedagogical descriptions of Mauritanian *Ḥassāniyya* (Francis and Hanchey, 1979) recognize four broad sub-dialects — Northern, Southern, Western, and Eastern Hassaniya — and further note variation between urban, rural, and nomadic speakers, while characterizing these local differences as primarily lexical and phonological rather than deeply structural. In CARDAMOM, we therefore adopt three geo-social annotation categories that are practical for the collected speech data and recognizable to native-speaker annotators: *Western*, *Northern*, and *Southern/Eastern*.

B.8.1 Western

The Western variety, *الغبلية/Gābla*, refers to the western and southwestern parts of Mauritania, including areas near the Senegal River. It is characterized by influence from Wolof and neighboring Sub-Saharan languages, along with local phonological and lexical features. Compared with the more desert-oriented eastern regions, this variety is also associated with a relatively more urban or commercial profile.

B.8.2 Northern

The Northern variety, *الساحل/Sāhil*, covers northern and northwestern Mauritania, including the Atlantic coastal strip. It is associated with stronger Bedouin and maritime influences, relatively conservative *Ḥassāniyya* features, and lexical items connected to nomadic and coastal life.

B.8.3 Southern

The Southern/Eastern variety, *الشَّرْج/Sharg*, covers eastern and southeastern Mauritania. It is char-

acterized by a highly homogeneous *Ḥassāniyya* profile, strong tribal and nomadic continuity, and comparatively conservative phonological and lexical features.

These categories should be understood as geo-social annotation categories rather than rigid dialect boundaries. As noted above, regional variation in *Ḥassāniyya* is not deeply structural; it is more visible in pronunciation, lexicon, and certain pragmatic or usage-related features. Phonologically, however, *Ḥassāniyya* differs from MSA in several important ways (Watson, 2002; Holes, 2004).

Phonologically, *Ḥassāniyya* shows several features that are important for micro-dialectal speech modeling. One of its conservative traits is the preservation of many Classical Arabic consonantal contrasts that have merged in several urban Arabic dialects, especially the interdental fricatives /θ/ ث, /ð/ ذ, and /ðˤ/ ظ. This is important for ASR because these sounds may remain phonetically salient in *Ḥassāniyya*, whereas other dialects often map them to /t, d, dˤ/ or /s, z, zˤ/ (Taine-Cheikh, 2007).

Another central variable is the reflex of Classical Arabic /q/. As in many Bedouin-type dialects, /q/ is often realized as a voiced velar stop /g/ in *Ḥassāniyya*. However, some descriptions also report alternations involving /q/ and /ɣ/, depending on the lexical item, register, and degree of classicization. The Peace Corps grammar notes that *Ḥassāniyya* pronunciation shows local peculiarities compared with Classical Arabic and explicitly highlights alternations involving *qāf*, /q/ ق, and *ghayn*, /ɣ/ غ. For computational transcription, this means that Arabic orthography may hide substantial phonetic divergence from MSA (Hanchey and Francis, 1979).

Ḥassāniyya also includes phonemes or marginal phonemes associated with contact and borrowing, especially /v/. This sound is absent from the traditional Classical Arabic phonemic inventory but is common in *Ḥassāniyya*, particularly in words of French, Berber, or other contact origin. The Peace Corps material identifies /v/ as a distinctive *Ḥassāniyya* feature not represented in the Classical Arabic alphabet (Hanchey and Francis, 1979). This also aligns with Taine-Cheikh’s broader account of contact-induced change in *Ḥassāniyya*, where contact with Berber and other languages has enriched both the phonological and morphological systems (Taine-Cheikh, 2018).

Beyond consonantal variation, *Ḥassāniyya* dif-

fers from MSA in syllable structure, vowel realization, stress, and reduction. The *Āmṣayt* book (Hayballah, 2024) and its review (Ould al Amir) note that *Ḥassāniyya* tends to shorten syllables and introduce consonant clustering or *sukūn*-like effects relative to the Classical/Standard system. These patterns directly affect how dialectal words should be written and transcribed. For ASR, this is especially important because a transcription policy normalized toward MSA may erase the phonological features needed for micro-dialect modeling.

The scholarly tradition on *Ḥassāniyya* is substantial but uneven. Early works were largely practical and administrative, providing grammatical sketches, vocabulary lists, dialogues, and common expressions for communication with local populations. Representative examples include (Faidherbe, 1887) *Langues sénégalaises*, (Marie-Bernard, 1893) Boisroux’s two-volume *Méthode d’arabe parlé: idiome du Sénégal*, and (Reynier, 1909)’s *Méthode pour l’étude du dialecte maure*. Later work became more systematic, especially (Cohen and Chennafi, 1963)’s study of the *Gǝbla* variety, which is described in the *Āmṣayt* book review (Ould al Amir) as a rigorous contribution to *Ḥassāniyya* phonetics and morphology. Catherine (Taine-Cheikh, 2007)’s work is particularly central because it covers *Ḥassāniyya* and Zenaga across phonetics, morphology, syntax, lexicon, prosody, and rhetoric. (Heath, 2004, 2003)’s work on *Ḥassāniyya* Arabic in Mali is also relevant for comparison, as it documents closely related Saharan varieties outside Mauritania.

B.9 Palestinian Micro-dialects

Palestinian Arabic forms a continuum of dialects across Palestine, with regional and social variations shaped by urbanization, village ties, and the dialect contact produced by forced displacement after the 1948 Nakba (Shahin, 2008; Cotter and Horesh, 2015). Traditional classifications often divide Palestinian colloquial speech into *urban* vs. *rural* types based on salient phonological features. However, this binary captures only part of the variation, as many speakers exhibit feature-mixing across local and social varieties, giving rise to several micro-dialects, including varieties associated with the Galilee, Carmel, the Nazareth region, the Jenin, Tulkarm and Nablus regions, Nablus city, the Ramallah and Jerusalem regions, the cities of Jerusalem and Jaffa, the Bethlehem and Hebron regions, Hebron city, the Gaza region, and the Negev

region (Haff et al., 2022; Jarrar et al., 2017). For analytical clarity, and given the limited linguistic resources available for each individual variety, this paper adopts a three-part classification: urban dialect, northern rural dialect, and southern rural dialect. This classification is not intended as a rigid geographic taxonomy; rather, it reflects recurring patterns of linguistic co-occurrence across phonological, morphosyntactic, and lexical features.

B.9.1 Madani – Urban Palestinian

The urban dialect encompasses the major Palestinian cities, particularly the coastal cities stretching from Akko to Gaza, as well as the inland centers of Hebron, Jerusalem, and Nablus. The speech of these cities reflects a linguistic ecology shaped by long-standing urbanization, social mobility, and trade networks (Shahin, 2008).

The main phonological feature of this variety is the realization of the letter (*qāf* قاف), which is realized as ([ʔ] ا) instead of ([q] ق). For example, the word (*qalb* قلب, heart) is pronounced (*ʔalb* اب) (Jarrar et al., 2017; Nayouf et al., 2023). Other distinctive phonological features in the urban dialect include the pronunciation of ث (*thā*) as ت (*tā*) and ذ (*dhā*) as د (*dā*). For example, the word (*kthīr* كثير, many) is realized as (*ktīr* كتير), and the word (*hatha* هذا, this) is realized as (*hada*) (Haff et al., 2022).

The 1948 Nakba and the 1967 war triggered large-scale forced displacement that significantly altered the dialectal composition of Palestinian cities. For example, refugees from Jaffa and Lod settled in Ramallah and Jerusalem; Hebronite families relocated to Jerusalem; and refugees from Jaffa, Asdod, Asqalan, and Majdal were displaced into Gaza (Shahin, 2008). The Ramallah dialect currently represents the most salient outcome of this process — a leveled urban koine, sometimes referred to informally as the “white” dialect, that bears notable similarity to the Amman urban koine.

B.9.2 Falāḥī - Northern Rural Palestinian

The Northern Rural Palestinian dialect is distributed across the northern West Bank and Galilee, extending from the Ramallah region through Salfit, Qalqilya, Tulkarm, and Jenin, and further north into Nazareth and the Galilee. These varieties exhibit distinctive phonological patterns closely associated with village identity. The most salient phonological feature is a chain shift involving (*qāf* ق) and (*kāf* ك). The historical ([q] ق) is frequently realized as ([k] ك), while ([k] ك) is in turn shifted to the affricate

([tʃ] تش) “ch”. This creates a systematic redistribution of phonological contrasts: the word (*qalb* قلب, ‘heart’) surfaces as (*kalb* كلب), while (*kalb* كلب, ‘dog’) surfaces as (*chalb* تشلب), with the original contrast preserved through affrication (Jarrar et al., 2014). The prominence of these features varies by subregion. In the Ramallah area, the affrication of (ق) into (“ch”) is more prominent, while in the Qalqilya region the realization of (ق) as [k] is prevalent. In Jenin, Nazareth, and the Galilee, speakers more frequently retain the uvular [q] realization, often with a stronger and more emphatic articulation. In addition to phonological variation, these dialects employ distinctive lexical items. The temporal adverb ‘now’ illustrates clear regional stratification: *hassa* (هنا) is prevalent in the northern West Bank, while *issa* (إسا) is characteristic of Nazareth and Galilee speech. Both forms contrast with *halla*’ (هالا) in urban dialects and *halhīn* (هلحين) in Southern Rural Palestinian varieties.

B.9.3 Falāḥī - Southern Rural Palestinian

In southern Palestine, the phonological and lexical profile of Palestinian Arabic shifts markedly. The Southern Rural Palestinian dialect is distributed across villages extending south of Jerusalem, through al-Ta’āmīrah and Banī ’Ubayd in the Bethlehem countryside, and further into the Hebron highlands. Its distribution extends southwest toward Beer al-Saba’, where Naqab Bedouin communities preserve strong tribal speech patterns, and westward into Gaza, where displaced southern families have contributed to the speech patterns of camps and coastal communities (Cotter, 2022; Shahin, 2008).

The most salient phonological characteristic of this variety is the realization of (*qāf* ق). Unlike Northern Rural Palestinian varieties, where [q] frequently shifts to [k], and urban varieties, where it commonly becomes a glottal stop [ʔ], Southern Rural Palestinian speech often realizes /q/ as ([g] غ). Thus, (*qalb* قلب, ‘heart’) may surface as (*galb* گلب) (Jarrar et al., 2017). Like other Palestinian dialect varieties, Southern Rural Palestinian extends beyond village and tribal boundaries, having been shaped by sustained contact with neighboring Bedouin dialects across southern Jordan, northern Saudi Arabia, and the Sinai Peninsula (Palva, 2008). Such contact has contributed to the variety’s distinctive phonological profile and its continued role as a marker of rural and tribal identity across southern Palestine.

B.10 Saudi Micro-dialects

The categorization of Saudi Arabian dialects into different regions is a conventional method used in modern sociolinguistic and phonetic research (Ingham, 1994; Prochazka, 1988). The dominant classification in current research encompasses the Najdi, Hijazi, Eastern, Northern, and Southern dialects. Each dialect reflects unique characteristics across the levels of linguistic analysis. The following is a summary of each dialect group.

B.10.1 Najdi

The Najdi dialect is spoken across central Saudi Arabia and can be divided into four main regional varieties (Ingham, 1994): Central Najdi (spoken in the heart of Najd), Northern Najdi (linked to the Jabal Shammar and ha'il area), Mixed Northern-Central Najdi (common in the Qassim region), and Southern Najdi (extending to southern areas such as Najran).

Northern Najdi is primarily spoken in the ha'il region and surrounding northern areas (Ingham, 1994). It retains many conservative and Bedouin features, including traditional vocabulary and expressions passed down through generations. The Mixed Northern-Central Najdi dialect, centered in the Qassim region, is characterized by distinctive pronunciation patterns, such as the affrication of certain consonants, and a unique melodic intonation. This variety reflects a blend of both northern and central Najdi, shaped by internal migration and trade (Ingham, 1994). Central Najdi, dominant in the capital city Riyadh and its surrounding towns, is considered the standard variety of Najdi Arabic. Due to Riyadh's political and economic prominence, this dialect has become associated with formal communication (Ingham, 1994; Prochazka, 1988). Finally, Southern Najdi, spoken along the southern edges of Najd and extending toward Najran, preserves older features that are less common in urban centers and shows some influence from southern Arabian dialects (Ingham, 1994).

In some Najdi dialects (more dominantly Qassimi dialect), the sound /k/ is often realized as [ts]; for example, a word pronounced as /kað.'ðɑ:b/ كذاب in MSA may be realized as [tsað.'ðɑ:b] تمذاب in Najdi speech. Similarly, the greeting /š.lo:ˈnak/ شلونك (when addressing a female) may be realized as [š.lo:ˈnats] شلونتس in some Najdi dialects.

B.10.2 Hijazi

Another major part of Saudi Arabia is the Hijaz region, which is a historically significant region in western Saudi Arabia that stretches along the Red Sea coast and encompasses the major cities of Mecca, Medina, Jeddah, Yanbu, and Taif, as well as the surrounding tribal areas (Destination KSA, 2023). Linguistically, the region is far from homogenous. The "Hijazi dialect" is not a single variety but rather a collection of dialects that can be grouped into two main categories (Sambas, 2016): 1) The Urban Hijazi which is spoken in the large cities of Mecca, Medina, Jeddah, Taif, and Yanbu. These cities have long attracted Arabs and Muslims, whether to live in proximity to the holy sanctuaries of Mecca and Medina or for economic and social opportunities, creating a speech variety shaped by both native residents and long-term settlers. This is the dialect that most people typically identify as "Hijazi Arabic." 2) The tribal Hijazi which is associated with the speech of Bedouin tribes inhabiting the broader Hijaz region. These dialects preserve Bedouin phonological and morphological features and are spoken by tribal groups whether in rural areas or, in some cases, within urban settlements.

In the Hijazi dialect, the sound /ð/ is often realized as [z]; for example, a word pronounced as /kað.'ðɑ:b/ كذاب is frequently pronounced as [kaz.'za:b] in Hijazi speech. Another characteristic feature is the substitution of /θ/ with [t]; for example, a word pronounced as /θa.la:θa/ تلاتة may be realized as [ta.la:ta] in Hijazi speech.

B.10.3 Eastern

The Eastern dialect of Saudi Arabia is primarily spoken in the Eastern Province, including key cities and regions such as Dammam, Al-Ahsa (Hofuf), Qatif, and Khobar. The Eastern dialect is very similar to other countries in the Gulf region, such as Bahrain and Qatar (Gulf Arabic Resources, 2023). This can be attributed to the boarder shared between Saudi and Bahrain and Saudi and Qatar.

Socially, the Eastern dialect is often described as slow in tempo, contrasting with the faster, more clipped rhythm of other dialects such as Najdi or Southern Arabic. Vowel quality in Eastern Arabic is notably distinct. The /a/ sound in medial syllables can be rounded, while in final position it may appear as a more open /a:/, imparting a unique musicality to the dialect. Additionally, the Eastern dialect is known for preserving some conservative phonetic and lexical features that have evolved or

disappeared in other Saudi dialects. For instance, certain traditional vocabulary items such as the word “simat” (meaning ‘dining mat’), are still used in the Eastern region but are rarely heard in other parts of Saudi Arabia. Additionally, a word such as /kaððab/ كذاب may be realized as [tʃaððab] تمذاب.

B.10.4 Southern

The Southern dialect of Saudi Arabia is spoken in the southern regions, notably in cities and areas such as Abha, Khamis Mushait, Jazan, Najran. This dialect is closest to the Yemeni dialect (Asiri, 2009). The southern dialect can be further divided into Asiri (spoken in the highlands near Abha), Tihami (along the Red Sea coastal plain), Najrani (in Najran), and Jizani (in Jazan) (Alqah-tani, 2015). The Southern dialect is often recognized for its fast and clipped rhythm. Phonological studies have shown that southern dialects may retain or develop consonantal and vowel features that are rare in other parts of Saudi Arabia, such as unique realizations of /q/.

The Asiri dialect is mostly spoken in cities such as Abha and Khamis Mushait. It maintains traditional Arabic features, including gender and plural distinctions in verbs and pronouns (Asiri, 2009). The Tihami dialect is spoken along the Red Sea coastal plain, spanning the lowlands of western Asir and part of Jazan. It is notable for its rapid, clipped rhythm and simplified syllable structure. The Najrani and Jizani dialects have a similar grammar and vocabulary to Yemeni Arabic, a result of longstanding cultural and geographic proximity to Yemen.

In some Southern dialects, the greeting /kay.fɑ ha:lak/ كيف حاله (when addressing a female) is often pronounced as [kayf ha:lɑʃ] كيف حالش. This reflects a common shift where the final “k” sound changes into a “sh” sound. This feature, known as *kashkasha*, is a well-known characteristic of speech of the Southern dialect.

B.10.5 Northern

The Northern dialect of Saudi Arabia is predominantly spoken in the northern regions, including cities and areas such as Tabuk, Arar, Al-Jawf, Rafha, and the surrounding rural communities. Al-Jawf dialect is influenced by its proximity to Jordan, Syria, and Iraq (Sandouka and Alotaibi, 2021). However, dialects spoken in Arar, Tabuk, and Rafha are very similar to Ha’il dialect.

Linguistically, the Northern dialect exhibits sev-

eral salient features. There is often a rising intonation in speech, and certain words or pronunciations may be hard for speakers from other Saudi regions to fully grasp. The Northern dialect is often associated with Bedouin heritage and retains many traditional speech patterns reflective of the nomadic lifestyle prevalent in these regions.

In some Northern dialects, the sound /k/ is often realized as [ts]; for example, a word pronounced as /kað.ʔɑ:b/ كذاب may be realized as [tsað.ʔɑ:b] >تمذاب in Northern speech, similar to some Najdi dialect. Similarly, the greeting /šax.ba:rak/ شخبارك (when addressing a female) may be realized as [šax.ba:rats] شخبارتس.

C Micro-Dialectal Overlap

C.1 Extended Corpus Statistics

Table 4 extends Table 1 (Section 6) with segment-duration range (*Min*, *Max*), average transcript length (*AVT*), vocabulary size and density (*U-Wds*, *Avg U-Wds/hr*), and speaking-rate proxies (*WPS*, *CPS*).

To examine fluid boundaries between micro-dialect labels, we analyze segments assigned to more than one micro-dialect within the same country. Table 5 reports the main pairwise overlaps. The highest overlap appears in Mauritania, where many segments are shared across Northern, Southern, and Western labels, reflecting the difficulty of separating highly related Hassaniya varieties in available public speech. Jordan also shows strong overlap, especially between Badawi–Falahi and Falahi–Madani, suggesting that Falahi functions as a bridge between Bedouin and urban varieties. In contrast, Saudi and Palestinian micro-dialects show much lower overlap, indicating more separated label assignments in the corpus.

D Speaker-Controlled Overlap Analysis

To check whether the multi-label overlap patterns discussed in Section 6.2 reflect genuine dialectal convergence rather than a small number of recurring speakers or channels, we cluster automatic speaker embeddings on the single-label segments of CARDAMOM (24,402 segments; multi-label segments are excluded to avoid conflating speaker overlap with label overlap). We extract embeddings with the off-the-shelf PYANNOTE We-Speaker ResNet34-LM speaker embedding model and group them with average-linkage clustering over cosine distance, yielding 19,770 estimated

Country	Micro-dialect	Segments	Total Hours	Mean	Min	Max	CS Hours	F/M	AVT	U-Wds	Avg U-Wds/hr	WPS	CPS

Table 5: Primary micro-dialectal intersections by region, reflecting the most fluid linguistic boundaries in the corpus.

distinct speakers overall. Table 6 reports unique speaker counts per micro-dialect, and Table 7 reports unique speaker counts within the multi-label intersections analyzed in Section 6.2 and Appendix C; the intersection counts are drawn from multi-label utterances only and are not independent cross-dialect evidence on their own, but are informative alongside the single-label counts.

E Annotation Schema

The complete annotation schema for each speech segment, including transcription, code-switching status, dialect and micro-dialect labels, speaker metadata, source video ID, and timestamp information, is shown in Figure 2.

E.1 Annotators per Micro-dialect

Table 8 reports the number of annotators covering each micro-dialect, together with the country-level totals reported in the main text. As noted in the Dataset Description, these per-micro-dialect counts are not mutually exclusive: several annotators were fluent in, and annotated, more than one micro-dialect within their country.

Country	Micro-dialect	Unique speakers
Egypt	Alexandrian	653
	Cairene	2,938
	Port Saidi	957
	Saidi	1,566
Jordan	Badawi	2,271
	Falahi	2,480
	Madani	1,346
Lebanon	B'albaki	72
	Chamali	590
	Jnoubi	825
Mauritania	Northern	61
	Southern	7
	Western	53
Palestine	Badawi	785
	Falahi	1,383
	Madani	471
Saudi Arabia	Eastern	717
	Hijazi	408
	Najdi	720
	Northern	334
	Southern	1,221

Table 6: Estimated unique speakers per micro-dialect (single-label segments only), from automatic speaker-embedding clustering.

Figure 2: Annotation schema for each speech segment. Each speech segment is associated with: (1) transcription, (2) code-switching status, (3) country-level dialect, (4) micro-dialect label(s), (5) perceived speaker gender, (6) YouTube video ID, and (7) start/end timestamps in the original source video.

F Representative Multi-label Dialect Segments

Table 9 provides representative examples of utterances annotated with more than one micro-dialect label. These cases illustrate that multi-label segments often reflect dialectal convergence rather than annotation ambiguity: a single utterance may contain lexical, phonological, or pragmatic cues shared by neighboring or socially related varieties. The examples span several countries and show overlap both within closely related regional varieties, such as Alexandrian–Port Saidi and Chamali–Jnoubi, and across broader intra-country dialect groupings, such as Badawi–Madani

Country	Intersection	Unique speakers
Mauritania	Northern–Southern	336
	Northern–Western	334
	Southern–Western	333
Jordan	Falahi–Madani	160
	Badawi–Falahi	157
	Badawi–Madani	22
Egypt	Alexandrian–Cairene	127
	Cairene–Port Saidi	58
	Alexandrian–Port Saidi	10
	Cairene–Saidi	9
Lebanon	Chamali–Jnoubi	55
	B'albaki–Chamali	53
	B'albaki–Jnoubi	53
Palestine	Badawi–Madani	6
Saudi Arabia	Hijazi–Najdi	6

Table 7: Estimated unique speakers within multi-label intersections (multi-label utterances only). Intersections with fewer than two estimated distinct speakers are omitted.

or Hijazi–Najdi. This supports our treatment of multi-label annotations as valid label memberships rather than disjoint classes, since they preserve naturally shared dialectal features in spontaneous speech. We give an English translation and a Latin transliteration for each example.

G Code-switching Examples

Table 10 illustrates several common types of Arabic–English/French code-switching observed in CARDAMOM across countries and micro-dialects. Some examples involve insertional or intra-sentential code-switching, where an English lexical item or phrase appears inside an otherwise Arabic utterance (e.g., *queue*, *social media*, and *my life*). Others are closer to inter-sentential code-switching, where a larger English phrase or discourse unit is produced alongside Arabic material, as in *it pays off*. We give an English translation and a Latin transliteration for each example.

H Train/Development/Test Splits

We divide the data of each country independently into train, development, and test sets. The three partitions are kept as close as possible in size, so that each contains approximately one third of the utterances from that country. An utterance is assigned to only one partition; it is never copied across train, development, and test. This country-wise design preserves the coverage of each country in all parti-

Country	Micro-dialect	Annotators
Egypt (5)	Cairene	3
	Saidi	1
	Port Saidi	1
	Alexandrian	2
Jordan (8)	Falahi	4
	Madani	2
	Badawi	2
Lebanon (2)	Chamali	1
	Jnoubi	2
	B'albaki	1
Mauritania (4)	Western	2
	Northern	2
	Southern	2
Palestine (3)	Falahi	2
	Madani	2
	Badawi	1
Saudi Arabia (9)	Southern	2
	Hijazi	2
	Najdi	3
	Northern	2
	Eastern	2

Table 8: Number of annotators covering each micro-dialect, grouped by country (country-level participant totals in parentheses). Counts are not mutually exclusive: annotators fluent in more than one micro-dialect are counted under each variety they annotated.

tions while preventing larger countries from determining the split sizes of smaller ones.

Micro-dialects are taken into account within each country. A split based only on the total number of utterances could leave a low-resource micro-dialect underrepresented in one partition, even when the country-level split sizes are balanced. We therefore balance the micro-dialect label memberships alongside the utterance counts. For each country, the target is to place approximately one third of the examples associated with each micro-dialect in train, one third in development, and one third in test. The resulting label counts are shown in Table 11.

This treatment also accounts for overlap between micro-dialects. Some utterances are annotated with more than one micro-dialect label, for example an utterance belonging to both Badawi and Falahi. Such an utterance remains a single example and is assigned to a single partition, but it contributes to the balance of both micro-dialect labels. We do not convert overlapping labels into a separate class, and we do not duplicate the utterance once per label. This preserves the original annotation structure while keeping the marginal distribution of each micro-dialect similar across the three parti-

tions.

I Text Preprocessing

We apply the same text preprocessing to both reference transcripts and system predictions before computing WER and CER. Specifically, we: (a) remove all types of punctuations; (b) remove Arabic diacritics, hamzas, and maddas; and (c) convert Eastern Arabic numerals to Western Arabic numerals (e.g., ٩٢ becomes 29). Unlike pipelines designed for monolingual Arabic, we preserve Latin characters because CARDAMOM contains code-switching, and deleting Latin text would remove valid lexical material from both references and hypotheses.

J ASR Adaptation Details

Table 12 reports aggregate WER/CER for all four systems, zero-shot vs. adapted (summarized in Section 7.2).

J.1 Checkpoints, Inference, and Fine-Tuning Setup

Table 13 reports checkpoint names, parameter counts, zero-shot inference settings, and adaptation hyperparameters for all four ASR systems (Section 7.1, 7.2). All zero-shot experiments use the original released checkpoints without additional training or in-context examples. Whisper-v3 and Seamless-v2 inference and adaptation use one NVIDIA A100 80GB GPU; OMNIASR adaptation uses four A100 80GB GPUs. Adaptation uses only the training split, with validation on the development split; the test split is untouched. No external language model, rescoring, metadata, or test-time adaptation is used.

J.2 Per-Micro-Dialect Confidence Intervals

Table 14 reports zero-shot WER with 95% bootstrap confidence intervals (2,000 resamples) per micro-dialect, on the test split described in Section 7.2. Because Jordan and Palestine share the label names Badawi, Falahi, and Madani, and Mauritania and Saudi Arabia both use Northern and Southern, we mark each country explicitly (e.g., (JOR) vs. (PAL)) and distinguish the Mauritanian rows with the *-Mau* suffix; all rows report country-specific micro-dialects. Confidence intervals reflect test-sample uncertainty, not training-seed variance, since each system is evaluated (or, for the adapted setting, fine-tuned) once. The broad ordering across dialects is stable, but narrow rankings

Region	Arabic	English	Latin transliteration	Multi-label
Jordan	يلا بخاطرك	Alright, see you!	Balā b-khāṭrak.	Badawi, Falahi
Jordan	اه والله مزبوط	Yes, that is correct.	Āh wallāh mazbūṭ.	Falahi, Madani
Egypt	استنى يابا	Wait, Dad.	Istanni yā bāba.	Alex., Port Saidi
Egypt	فلوس باباكي متلزمناش	Your father’s money does not concern us.	Fulūs bābāki ma tilzam-nāsh.	Alex., Cairene
Saudi Arabia	تماما ينطبق نفس الشي على الرجال	Exactly, the same thing applies to men.	Tamāman yinṭabiq nafs il-shay ‘ala al-rijāl.	Hijazi, Najdi
Palestine	قد يش يعني؟ قد البحر. عاد ليش خايف؟	How much? As big as the sea. Why are you afraid?	Qaddesh ya’ni? Add il-baḥr. ‘Ad lēsh khāyef?	Badawi, Madani
Lebanon	بتزين السفرة بهالاشيا	It decorates the table with these things.	Btzayyen is-sufra b-hal-ashya.	Chamali, Jnoubi
Mauritania	شوف انا اولدت ف ولاية انشيري	Look, I was born in Inchiri state; I am one of the people of Inchiri.	Shūf, ana wladt f wilāyat Inchiri; ana wāhed min ahl Inchiri.	South., North.

Table 9: Examples of multi-label segments from the CARDAMOM corpus showing how dialects can overlap in real use, with English translation and Latin transliteration.

Dialect	Arabic	English translation	Latin transliteration
Egypt–Cairene	انت كويس؟	Morning	Morning, inta kwayyis?
Jordan–Madani	هالا لا هيه مش ست سنين أكيد بس هالا لا هيه مش ست سنين أكيد بس it pays off	Well, no, it definitely isn’t six years, but it pays off in the end.	Halla la, hiyye mish sitt snīn akīd, bas it pays off bil-ākhir.
Saudi–Najdi	امس كنت في محل عنده براكا	Yesterday, I was at a store that had a queue outside.	Ams kunt fī maḥall ‘indah queue barra.
Palestine–Falahi	انا بدي احس بحياتي انا بطلت احس ب	I want to feel alive; I no longer feel connected to my life.	Ana biddi aḥiss bi-ḥayātī, ana baṭallt aḥiss bi-my life.
Lebanon–B’albaki	كثير يعني عطول فأنا نقلت عال	A lot, basically all the time, so I moved to social media.	Ktīr ya’ni ‘a-ṭūl, fa-ana na’alt ‘al-social media.
Mauritania–Northern	Instagram وابدأت نعدلها على بعد ذاك كانوا معاي شباب	I started editing it on Instagram; after that, some young men were with me.	W-ibdīt n’addilha ‘alā Instagram, ba’d dhāk kānū ma’īya shabāb.

Table 10: Representative Arabic–English code-switched utterances with English translation and Latin transliteration.

on the smallest subsets (B’albaki, Saudi Northern) fall within overlapping intervals and should not be treated as conclusive.

Table 15 reports the corresponding WER after adaptation (Section 7.2), using the same micro-dialect grouping and test sets as Table 14.

K Micro-Dialect Identification Details

This section provides full task definitions, training details, and per-country breakdowns for the micro-dialect identification (MDI) experiments summarized in Section 7.3.

K.1 Tasks

We define three audio-based identification tasks over the standard CARDAMOM train/development/test splits (Appendix H): (i) *country-dialect identification*, a 6-way classification over Egypt, Jordan, Lebanon, Mauritania, Palestine, and Saudi Arabia; (ii) *global micro-dialect identification*, a 21-way classification over all micro-dialect labels pooled across countries; and (iii) *country-conditioned micro-dialect identification*, which predicts the micro-dialect given the gold country label.

K.2 Systems

Zero-shot Qwen3-Omni. We prompt Qwen3-Omni with the audio segment and a closed la-

Country	Micro-dialect	All	Train	Dev.	Test
Egypt	Alexandrian	848	282	283	283
	Cairene	3,871	1,290	1,291	1,290
	Port Saidi	1,124	375	375	374
	Saidi	1,735	578	578	579
Jordan	Badawi	2,899	967	966	966
	Falahi	3,276	1,092	1,092	1,092
	Madani	1,909	637	636	636
Lebanon	B'albaki	258	86	86	86
	Chamali	1,105	368	369	368
	Jnoubi	1,464	487	488	489
Mauritania	Northern	1,205	402	401	402
	Southern	1,126	376	375	375
	Western	1,210	402	404	404
Palestine	Badawi	864	288	288	288
	Falahi	1,564	521	522	521
	Madani	537	179	179	179
Saudi Arabia	Eastern	956	319	318	319
	Hijazi	1,413	471	471	471
	Najdi	1,089	363	363	363
	Northern	514	172	171	171
	Southern	1,423	473	475	475

Table 11: Micro-dialect label memberships in the country-wise splits. Counts are label memberships rather than disjoint utterance counts: an utterance with two micro-dialect labels contributes to both corresponding rows but remains a single utterance in one partition.

bel set for each task, without any transcript or metadata, and parse the returned label. **LoRA fine-tuned Qwen3-Omni.** We fine-tune the same model with LoRA adapters (8.65M trainable parameters) jointly on all three tasks, using the same training split, test set, prompts, and decoding as the zero-shot setting. **Whisper-large-v3 classifier.** We train a dedicated classifier with a shared Whisper-large-v3 audio encoder and three jointly trained classification heads: country, global micro-dialect (multi-label), and country-conditioned micro-dialect (multi-label).

K.3 Results

Table 16 reports accuracy and macro-F1 for all three systems and tasks, summarized in Section 7.3. Fine-tuning Qwen3-Omni improves accuracy by 47.72 points (95% CI [46.61, 48.85]) on country identification, 58.46 points (95% CI [57.32, 59.59]) on global micro-dialect identification, and 43.65 points (95% CI [42.43, 44.84]) on country-conditioned identification; all improvements are statistically significant. Hierarchical consistency, the rate at which independently predicted country and micro-dialect labels agree, rises from 33.67% (zero-shot) to 95.48% (LoRA fine-tuned). The Whisper-v3 classifier further outperforms fine-

Model	Setting	WER (95% CI)	CER (95% CI)
Whisper-v3	Zero-shot	55.38 [53.75, 57.07]	29.40 [28.07, 30.90]
	Adapted	46.03 [44.70, 47.42]	21.53 [20.44, 22.78]
Seamless-v2	Zero-shot	53.13 [52.06, 54.26]	28.84 [27.78, 30.00]
	Adapted	52.48 [50.57, 54.58]	25.38 [23.93, 26.90]
OmniASR-LLM	Zero-shot	43.47 [42.67, 44.29]	20.67 [19.88, 21.52]
	Adapted	35.21 [34.40, 36.09]	16.04 [15.27, 16.90]
OmniASR-CTC	Zero-shot	58.17 [57.25, 59.12]	33.78 [32.56, 35.19]
	Adapted	40.83 [40.08, 41.61]	16.08 [15.46, 16.77]

Table 12: Aggregate WER and CER (%; lower is better) over the 9,152 unique test utterances under zero-shot and adapted settings. Multi-label utterances are counted once. Bracketed values are 95% percentile bootstrap confidence intervals obtained from 2,000 utterance-level resamples of the test set. Adapted models were trained once; therefore, the intervals quantify test-sample uncertainty but not variation across training runs. The best adapted result in each column is shown in **bold**.

tuned Qwen3-Omni by 6.39 accuracy points (95% CI [5.73, 7.05]) on country identification, 7.91 points (95% CI [7.07, 8.76]) on global micro-dialect identification, and 3.83 points (95% CI [3.12, 4.54]) on country-conditioned identification.

Table 17 breaks down country-conditioned micro-dialect identification accuracy by country for the LoRA fine-tuned Qwen3-Omni model and the Whisper-v3 classifier. The largest gain over zero-shot was observed for Saudi Arabia, where Qwen3-Omni accuracy rose from 20.31% (zero-shot) to 93.64% (LoRA fine-tuned), followed by Palestine, Jordan, and Lebanon; Mauritania was the only country without an improvement over its zero-shot performance, consistent with the very limited web-scale representation of Hassaniya speech noted throughout this paper.

L Dialectness Result

Figure 3 shows ALDi dialectness scores (Keleg et al., 2023) per micro-dialect group; MSA segments score lowest (8.5%), multi-label intersections highest (up to 97.1%), and Mauritanian varieties occupy the lower end (36.9–53.4%), consistent with their MSA-proximate broadcast sources.

Many of the highest dialectness scores correspond to multi-label dialect–dialect intersections, such as Egypt-Alexandrian–Port Saidi (97.1%) and Jordan-Badawi–Madani (88.9%), suggesting that overlapping labels often capture strongly dialectal utterances shared across neighboring or socially related varieties rather than neutral or MSA-like speech. Dialectness and ASR difficulty largely agree for highly dialectal, high-WER varieties such as Egypt-Port Saidi, Egypt-Saidi, and Saudi-

System	Checkpoint / Parameters	Zero-shot Inference	Adaptation
Whisper-v3	openai/whisper-large-v3, 1.55B	Greedy Arabic transcription; batch 16	LoRA on Q/V projections: rank 16, $\alpha=32$, dropout 0.05; 3 epochs; batch 8, 4-step accumulation; LR $1e-4$
SeamlessM4T-v2	facebook/seamless-m4t-v2-large, 1.50B S2T parameters	Greedy speech-to-text with Arabic target; batch 8	LoRA on Q/V projections: rank 16, $\alpha=32$, dropout 0.05; 3 epochs; batch 4, 4-step accumulation; LR $1e-4$
OmniASR-LLM-v2	omniASR_LLM_7B_v2, $\approx 7.80B$	Autoregressive one-best decoding, arb_Arab; batch 2	Full fine-tuning, 1,200 steps; LR $1e-5$; BF16 FSDP on $4 \times A100$; 8-step accumulation

Madani (JOR)	632	39.58 [34.40, 47.86]	40.98 [38.36, 43.82]	28.87 [27.19, 30.62]	49.38 [46.24, 52.93]
B'albaki (LEB)	81	70.32 [58.54, 85.04]	74.42 [67.67, 80.70]	58.08 [48.38, 71.99]	88.16 [82.45, 92.18]
Chamali (LEB)	362	60.28 [56.62, 64.72]	66.23 [62.37, 69.60]	42.30 [40.19, 44.56]	81.25 [77.67, 84.36]
Jnoubi (LEB)	478	55.28 [49.94, 61.64]	57.43 [52.24, 63.52]	45.30 [41.96, 49.33]	61.45 [57.60, 65.06]
Northern-Mau (MAU)	500	86.40 [81.02, 92.96]	80.82 [78.38, 83.32]	70.90 [68.90, 72.88]	85.44 [83.51, 87.19]
Southern-Mau (MAU)	475	86.68 [81.38, 93.07]	81.93 [79.11, 85.00]	71.14 [69.30, 73.27]	85.86 [84.08, 87.62]
Western-Mau (MAU)	514	86.34 [81.19, 92.47]	82.40 [79.29, 86.14]	71.06 [69.09, 72.93]	85.80 [84.09, 87.49]
Badawi (PAL)	287	46.88 [43.46, 50.80]	44.91 [41.53, 48.72]	45.94 [41.31, 51.32]	49.38 [46.21, 52.55]
Falahi (PAL)	510	52.40 [48.27, 57.98]	48.01 [45.46, 50.62]	46.51 [43.24, 50.21]	51.99 [49.46, 54.67]
Madani (PAL)	179	48.43 [43.83, 53.38]	47.82 [41.07, 55.82]	51.51 [38.84, 68.95]	49.66 [44.78, 54.90]
Eastern (KSA)	312	48.39 [42.85, 56.23]	43.69 [40.82, 47.02]	35.48 [32.68, 38.59]	58.06 [54.03, 61.90]
Hijazi (KSA)	471	41.72 [40.10, 43.27]	40.12 [37.79, 42.69]	36.04 [34.45, 37.66]	43.87 [41.76, 46.09]
Najdi (KSA)	363	53.77 [47.95, 61.70]	52.29 [49.02, 55.88]	39.59 [37.30, 42.02]	61.79 [57.62, 65.67]
Northern (KSA)	170	105.73 [82.43, 135.58]	89.03 [80.28, 100.59]	68.06 [63.84, 72.52]	80.31 [76.95, 83.42]
Southern (KSA)	474	56.26 [50.76, 62.95]	58.35 [53.13, 63.11]	42.17 [38.52, 45.71]	70.10 [64.40, 74.68]

Table 14: Zero-shot WER (%) with 95% bootstrap confidence intervals per micro-dialect. N is the number of test utterances evaluated for that micro-dialect (single- and multi-label).

Northern (Table 2), but they diverge for capital-associated varieties: Jordan-Madani and Egypt-Cairene score highly on dialectness yet remain comparatively easy to recognize, showing that a transcript can be strongly dialectal by ALDi’s measure while still being easy for current ASR systems, most likely because capital-city varieties are better represented in the web-scale speech and text data these models were pretrained on.

Micro-dialect	N	Whisper-v3	Seamless-v2	OmniASR-LLM	OmniASR-CTC
Alexandrian (EGY)	281	45.68 [42.61, 48.97]	47.02 [40.55, 57.34]	30.94 [28.11, 34.02]	41.58 [38.63, 44.74]
