EvoDuet Project Page

Abstract

Evolutionary search with large language models (LLMs) can stall when progress requires external knowledge the model lacks. Supplying relevant documents helps, but simply adding web search tool can keep returning the same pages as solutions change. We introduce **EVODUET**, a bi-level optimization method that co-evolves *solutions* and *search queries* with fixed model parameters. At each iteration, a retrieval gate lets the LLM assess its knowledge gap and choose to retrieve new documents, reuse stored ones, or proceed without them. An inner loop refines queries and ranks documents by the solution scores they are predicted to yield; an outer loop generates candidates in parallel from these documents and records the evaluated outcomes for later searches. Across 21 optimization tasks with one candidate per iteration, EVODUET raises OpenEvolve’s normalized discovery gain from 74.1% to 78.0% with GPT-5.6-Luna and from 61.3% to 82.3% with Gemini-3.8-Flash, whereas Qwen3.5-9B does not benefit. Our best runs surpass the previously reported best scores on eight tasks, including Swap Reduction on Q20 and Rosetta, and match them on three more. EVODUET also improves with other scaffolds (e.g., Top- K , EvoX) on Sums/Diffs and Denoising, demonstrating its applicability across evolutionary search scaffolds.

1. Introduction

Evolutionary search scaffolds driven by large language models (LLMs) (Romera-Paredes et al., 2024; Novikov et al., 2025) have begun to discover new solutions to optimization tasks such as the Erdős minimum-overlap problem (Erdős, 1955), GPU kernel design (Ouyang et al., 2025), and single-cell RNA-seq denoising (Yuksekgonul et al., 2026). In these tasks, an evaluator can score any candidate solution, but the optimal solution cannot be computed directly (Kirkpatrick et al., 1983). Scaffolds therefore iterate: the LLM proposes candidates, the evaluator scores them, and high-scoring candidates seed the next iteration.

Most scaffolds (Sharma, 2025; Lange et al., 2025; Cemri et al., 2026) run only this *solution loop*. Others keep the solution loop from saturating by wrapping additional loops around it, a design we call *Loop Packing* (Figure 1). For example, EvoX (Liu et al., 2026a) adds a strategy loop that revises the search strategy when progress stagnates. However, every loop packed so far draws on the same two sources of knowledge: the run’s evolutionary history and the LLM’s parametric knowledge. The search is therefore **closed**, and it stalls when progress requires external knowledge that neither source contains (e.g., how to use a newer library version). Human scientists, by contrast, consult the literature and search again as new knowledge gaps emerge.

Our preliminary analysis (§ 2.3) shows that external knowledge helps LLM-driven search, but not automatically. Supplying task-relevant and helpful documents at every iteration (oracle documents) raises OpenEvolve’s average Normalized Discovery Gain (NDG) on

Figure 1: Packing loops of multiple optimization scaffolds

*Co-second authors with equal contribution, listed alphabetically by surname.

Figure 2: EVODUET co-evolves solutions and web queries. The inner loop evolves queries; the outer loop uses retrieved documents to revise and evaluate solutions. The Swap Reduction example illustrates *method transfer* (the most common of the six behaviors analyzed in Section 5.1): the model applies retrieved routing principles to prioritize gates closer to execution (iteration 5) and penalize reversing the last SWAP (iteration 66). At iteration 64, the gate reuses stored documents without a new web search. The best router found in this run uses 14,835 Q20 SWAPs, 2.31% fewer than the released SimpleTES program (WILL Team, 2026) (15,186) under the same evaluator.

31 tasks by 10.3% with Qwen3.5-9B and 4.0% with GPT-5.6-Luna. Two further observations show that turning such knowledge into progress takes more than a search tool: First, the LLM needs room to explore: on Sums/Diffs, oracle documents help only when the LLM generates eight candidates per iteration rather than one. Second, queries must evolve with the solution: on Denoising, an LLM that searches inside the solution loop mostly retrieves pages it has already seen (88.1% of returned URLs) and stops improving after 50 iterations. We therefore co-evolve web search queries with solutions (Figure 1), making the search **open**.

We introduce **EVODUET**, a bi-level optimization method that co-evolves solutions in an outer loop and web search queries in an inner loop, with the LLM’s parameters fixed. A knowledge-gap-based retrieval gate connects the loops: at each iteration, the LLM assesses what it still needs to know to improve the current solution (its knowledge gap) and decides whether to retrieve new documents, reuse stored ones, or proceed without documents. When it retrieves, the inner loop constructs queries targeting the gap, searches the web, and ranks documents by *hypothetical evidence scoring*, which predicts the evaluator score of a candidate built on each document. These predictions and the updated knowledge state steer the next round of queries without evaluating any candidate. Given documents, the outer loop generates candidates in parallel and records the documents with the evaluated outcome to guide later searches. Figure 2 illustrates this interplay on Swap Reduction (quantum compilation).

We evaluate EVODUET with OpenEvolve on 21 optimization tasks. With one candidate per iteration, it raises overall NDG from 74.1% to 78.0% with GPT-5.6-Luna and from 61.3% to 82.3% with Gemini-3.8-Flash, and parallel generation improves it further. Qwen3.5-9B does not benefit, even though oracle documents help it: it often leaves retrieved methods unused or misimplemented (26% of sampled revisions), suggesting that co-evolution requires a model that can both find and apply evidence. The best runs of EVODUET surpass the previously reported best scores on eight tasks and match them on three more; on Denoising, EVODUET surpasses SimpleTES (WILL Team, 2026) at 6.9× lower estimated cost. It also improves other scaffolds, Top-*K* and EvoX, on Sums/Diffs and Denoising, showing that the search loop can be packed alongside existing loops.

Finally, we analyze how retrieved documents shape the search. Candidates improve on their parent in 67.1% of iterations that retrieve a document predicted to beat the parent, compared with 52.1% of iterations without documents. The most common use of documents is *method transfer*, in which the model applies a retrieved method to its solution (55 of 82

Figure 3: OpenEvolve with and without oracle documents on 31 optimization tasks using Qwen3.5-9B and GPT-5.6-Luna. (a) Average NDG across tasks. (b) Per-task ΔNDG versus baseline NDG, with bin medians pooled across models. Shading marks baseline NDG below 5% or at least 80%; hollow markers denote simple tasks. The dashed line shows the gain needed to reach 100% NDG. (c) Per-task ΔNDG in descending order. Legends count tasks with NDG increases (improved) or decreases (degraded) of more than 1%; shading indicates changes within $\pm 1\%$.

runs). Yet documents predicted to help can also yield much worse candidates (29 of 82 runs), so predicted gains must still be validated by the evaluator.

2. Analysis of Web Search in Scientific Discovery

2.1. Preliminaries: Evolutionary Search Scaffold

An optimization task $\tau = (I, x_0, \mathcal{E})$ consists of an instruction I , an initial solution x_0 , and a deterministic, verifiable evaluator $\mathcal{E}(x) \in \mathbb{R}$. The goal of an evolutionary search scaffold is to find $x^* = \arg \text{opt}_{x \in \mathcal{X}} \mathcal{E}(x)$, where $\text{opt} \in \{\max, \min\}$ and $\mathcal{X} = \{x_0, \dots, x_T\}$ is the set of solutions explored within a search budget of T . The task determines the optimization direction (e.g., minimizing the c_5 bound in the Erdős minimum overlap problem). At each iteration, the evolutionary search scaffold (Romera-Paredes et al., 2024; Novikov et al., 2025; Sharma, 2025; Liu et al., 2026a) selects a parent solution x_t and its evolutionary history $\mathcal{H}_t$ from its solution database (*a.k.a.* population) $\mathcal{D}_p$ under a policy ϕ , forming the context $c_t = [\mathcal{H}_t; x_t]$. A frozen LLM $\mathcal{M}_\theta$, serving as the mutation operator, generates a candidate solution $x_{t+1} \sim \mathcal{M}_\theta(I, c_t)$, which the evaluator $\mathcal{E}$ then scores. Based on the selection policy ϕ , the candidate solution x_{t+1} is then either added to the population $\mathcal{D}_p$ or discarded. We call x^* a *discovery* if it improves upon the previous best-known solution x_{sota} , i.e., $\mathcal{E}(x^*) > \mathcal{E}(x_{\text{sota}})$ for maximization tasks, with the inequality reversed for minimization tasks.

2.2. Experimental Setup

Tasks. We evaluate on 31 optimization tasks spanning simple scientific optimization (10), quantum compilation (1), astrodynamics (5), scientific algorithms (1), AI foundations (4), mathematics (8), and algorithm engineering (2). Detailed task descriptions are provided in Appendix C.1.

Baselines. We use Qwen3.5-9B (Team, 2026) and GPT-5.6-Luna (OpenAI, 2026) as the LLM $\mathcal{M}_\theta$ in OpenEvolve. For each model, we compare (1) OpenEvolve and (2) OpenEvolve with oracle documents supplied to the LLM at every iteration t . Appendix C.2 describes how we construct the oracle documents. For robustness, we run each baseline with four different random seeds.

Evaluation Metric. Since evaluator score ranges vary across tasks, we report *Normalized Discovery Gain* (NDG) to compare optimization progress on a common scale. NDG measures the percentage of the gap between the initial and SOTA scores closed by a run: $\text{NDG} = \frac{\mathcal{E}(x_{\text{best}}) - \mathcal{E}(x_0)}{\mathcal{E}(x_{\text{SOTA}}) - \mathcal{E}(x_0)} \times 100$, where x_{best} is the best-scoring solution in $\mathcal{X}$, and x_{SOTA} is the best program reported in prior work (WILL Team, 2026). Higher NDG indicates greater progress toward SOTA performance.

2.3. Does web search help scientific discovery?

Oracle documents improve optimization on average, but their benefits vary across models and tasks. As shown in Figure 3a, oracle documents raise the average NDG of Qwen3.5-9B by 10.3% and that of GPT-5.6-Luna by 4.0%. The smaller gain for GPT-5.6-Luna likely reflects limited headroom: OpenEvolve alone already reaches at least 95%

Figure 4: Effects of parallel generation and query evolution with GPT-5.6-Luna. (a) NDG of OpenEvolve on Sums/Diffs (mathematics) with and without oracle documents, using $N = 1$ or $N = 8$ candidates per iteration. (b) Cumulative number of search queries. (c) Number of distinct URLs returned. (d) Held-out NDG of the best program for each method.

NDG on 16 of the 31 tasks. On these tasks, oracle documents change NDG by only 0.1% on average (Figure 3b). Although oracle documents lead to 100% NDG primarily on simple optimization tasks, their benefits also extend to challenging tasks. For example, on Swap Reduction (quantum compilation), oracle documents increase NDG by 6.1% for Qwen3.5-9B and 41.5% for GPT-5.6-Luna (Figure 3c). However, these benefits are not universal: oracle documents lower NDG by more than 1% on 8 and 4 of the 31 tasks for Qwen3.5-9B and GPT-5.6-Luna, respectively, including decreases of 9.0% and 23.3% on Rosetta. Full results are provided in Appendix D.1.

LLMs may need more opportunities to benefit from oracle documents. The mixed effects of oracle documents raise a question: does the LLM lack the ability to use oracle documents, or does it lack sufficient opportunities to act on them? To examine this, we generate N candidates in parallel at each iteration t from the same context c_t . On Sums/Diffs, oracle documents offer no improvement at $N = 1$ (14.8% NDG with oracle documents versus 15.4% without), but increase NDG from 25.8% to 40.7% at $N = 8$ (Figure 4b). This suggests that the LLM can benefit from oracle documents when given more opportunities to explore strategies grounded in them. Additional results are provided in Appendix D.2.

Without query evolution, in-loop web search repeatedly retrieves the same pages and stalls. On Denoising with GPT-5.6-Luna, we equip OpenEvolve with Tavily¹ as an in-loop search tool (*joint-level*), allowing the LLM to construct its own queries during solution optimization. We compare this baseline with EVODUET, which evolves queries based on the LLM’s knowledge gap through bi-level co-evolution. Over 100 iterations, joint-level search uses the tool in 99 iterations and produces 185 queries, compared with 201 for EVODUET (Figure 4b). However, it retrieves only 85 distinct URLs, compared with 248 for EVODUET (Figure 4c); 88.1% of its returned URLs have appeared before, compared with 62.4% for EVODUET. Moreover, joint-level search stops improving after iteration 50, with its best program achieving a held-out NDG of 27.7%, compared with 84.5% for EVODUET (Figure 4d). These results suggest that evolving what to ask based on the LLM’s knowledge gap helps it search for external knowledge more effectively, enabling it to find better solutions.

Takeaways: Web search benefits from broader exploration and query evolution

- Oracle documents increase average NDG across the 31 tasks, with a larger gain for the smaller model (+10.3% vs. +4.0%).
- More opportunities for exploration can help LLMs use oracle documents: on Sums/Diffs, oracle documents improve NDG by 14.9% with eight parallel candidates per iteration.
- Query evolution helps sustain progress: with comparable query counts on Denoising, joint-level search repeatedly retrieves the same pages and stalls, whereas bi-level search, which evolves queries based on the LLM’s knowledge gap, retrieves about 2.9× as many distinct pages and increases NDG by 56.8%.

3. EVODUET

3.1. An Overview of EVODUET

We formulate discovery as a bi-level optimization problem with an outer loop that evolves solutions and an inner loop that evolves queries for web search. As shown in Figure 5, EVODUET has three main components:

¹<https://www.tavily.com/>

Figure 5: Overview of EVODUET. The outer loop evolves solutions, while the inner loop evolves web search queries using predicted solution scores. A knowledge-gap-based retrieval gate links the two loops by deciding whether to retrieve new documents (**RETRIEVE**), reuse stored documents (**LOOK-UP**), or proceed without documents (**NO-OP**).

- **Solution Optimization Loop (outer, § 3.2):** The outer loop follows the scaffold’s evolutionary loop (§ 2.1) to evolve solutions. At iteration t , the selection policy ϕ selects a parent solution x_t and its evolutionary history $\mathcal{H}_t$ from the population $\mathcal{D}_e$, and the LLM $\mathcal{M}_\theta$ generates a candidate solution $x_{t+1} \sim \mathcal{M}_\theta(I, c_t, \mathcal{S}_t)$, where $\mathcal{S}_t$ is either empty or a set of retrieved web documents.
- **Knowledge Gap-based Retrieval Gating (§ 3.3):** This component connects the outer and inner loops, enabling their co-evolution. Based on gaps in the LLM $\mathcal{M}_\theta$ ’s current knowledge status, it determines whether to invoke the inner loop for web search.
- **Query Optimization Loop (inner, § 3.4):** The inner loop evolves web search queries to retrieve documents $\mathcal{S}_t$ that provide the external knowledge needed to generate an improved candidate solution x_{t+1} .

Both loops share the task objective $\mathcal{E}$, with query quality defined by the performance of the candidate solution generated from the retrieved documents. Let $\mathcal{S}_t(q)$ denote the documents retained from query q and $x_{t+1}(q) \sim \mathcal{M}_\theta(I, c_t, \mathcal{S}_t(q))$ the resulting candidate. The ideal bi-level optimization is formulated as

$$\underbrace{x^* = \arg \text{opt}_{x \in \mathcal{X}} \mathcal{E}(x)}_{\text{outer: solution optimization}} \quad \text{s.t.} \quad \underbrace{q_t^* = \arg \text{opt}_{q \in \mathcal{Q}_t} \mathcal{E}(x_{t+1}(q))}_{\text{inner: query optimization}}, \quad x_{t+1} \sim \mathcal{M}_\theta(I, c_t, \mathcal{S}_t(q_t^*)), \quad (1)$$

where $\mathcal{X} = \{x_0, \dots, x_T\}$ is the set of solutions explored within budget T , and $\mathcal{Q}_t$ is the set of admissible queries at iteration t . However, the inner objective $\mathcal{E}(x_{t+1}(q))$ is observable only after the corresponding candidate has been generated and evaluated. Repeating this process for every query within the inner loop would be costly. We therefore approximate the inner optimization in Eq. 1 using $\mathcal{M}_\theta$ to **predict the candidate score** that the retrieved documents would yield. Denoting this score predictor by $\hat{\mathcal{E}}_\theta$, the approximate inner optimization can then be reformulated as $\hat{q}_t = \arg \text{opt}_{q \in \mathcal{Q}_t} \hat{\mathcal{E}}_\theta(I, c_t, \mathcal{S}_t(q))$. The detailed algorithm is presented in Algorithm 1.

3.2. Outer Loop: Solution Optimization

The outer loop follows the scaffold’s typical evolutionary procedure (§ 2.1), but differs in the inputs provided to the LLM $\mathcal{M}_\theta$ during candidate generation. When web documents $\mathcal{S}_t$ are provided, the LLM $\mathcal{M}_\theta$ generates a candidate solution $x_{t+1} \sim \mathcal{M}_\theta(I, c_t, \mathcal{S}_t)$, which is then evaluated by $\mathcal{E}$ and retained or discarded according to ϕ . The web documents $\mathcal{S}_t$ are stored in the search database $\mathcal{D}_s$ together with the candidate’s actual evaluator score $\mathcal{E}(x_{t+1})$. This

stored information is used to decide whether to reuse existing documents in $\mathcal{D}_s$ through a search database $\mathcal{D}_s$ lookup, retrieve additional knowledge from the web, or skip the inner loop.

Gated parallel candidate solution generation. In Section 2, we observe that parallel scaling with rich oracle documents enables the LLM $\mathcal{M}_\theta$ to explore diverse approaches and find better solutions. Motivated by this observation, EVODUET generates N_t candidates in parallel from the same input prompt, with $N_t = N$ for [LOOK-UP](#) or [RETRIEVE](#) and $N_t = 1$ for [NO-OP](#). Candidate generation and selection are formulated as

$$x_{t+1}^{(n)} \sim \mathcal{M}_\theta(I, c_t, \mathcal{S}_t), \quad n = 1, \dots, N_t, \quad x_{t+1} = \arg \operatorname{opt}_{x \in \mathcal{C}_t^{\text{valid}}} \mathcal{E}(x), \quad (2)$$

where $\mathcal{C}_t^{\text{valid}}$ is the set of valid candidates (i.e., those that encounter no errors, such as evaluator errors) among the N_t generated solutions. Each candidate is evaluated, and only the best valid solution is passed to ϕ as x_{t+1} .

3.3. Knowledge-Gap-Based Retrieval Gating

The gate allows $\mathcal{M}_\theta$ to determine *when* to search by assessing whether it needs new external knowledge to improve the current solution x_t , can reuse information stored in $\mathcal{D}_s$, or can evolve the solution using only its internal knowledge. At each iteration, given the context c_t and the documents most recently stored in $\mathcal{D}_s$, $\mathcal{M}_\theta$ outputs its current knowledge state K_t and a retrieval decision g_t :

$$(K_t, g_t) = \text{GATE}_{\mathcal{M}_\theta}(c_t, \mathcal{D}_s), \quad g_t \in \{\text{NO-OP}, \text{LOOK-UP}, \text{RETRIEVE}\}. \quad (3)$$

The knowledge state K_t distinguishes the model’s existing knowledge, findings from previous searches and experiments, and unresolved questions about x_t that define the current knowledge gap. The gate selects [NO-OP](#) when the model’s knowledge suffices, [LOOK-UP](#) when stored documents provide the missing knowledge, and [RETRIEVE](#) when neither source is sufficient. Under [LOOK-UP](#), the selected documents are included in the solution prompt without a new web search. This makes retrieval responsive to the current knowledge gap and enables the reuse of previously retrieved evidence. The results in Table 1b show that knowledge-gap-based gating is more effective than the heuristic gating based on stalled progress used in EvoX (Liu et al., 2026a).

3.4. Inner Loop: Query Optimization

When $g_t = \text{RETRIEVE}$, the inner loop approximates the query optimization in Eq. 1 over R inner rounds within the current outer iteration t , without generating or evaluating candidate solution.

Population state descriptor. Following EvoX (Liu et al., 2026a), the inner loop first computes a population state descriptor, $\text{stats}(\mathcal{D}_p)$, comprising deterministic statistics of the retained population, its score distribution, recent parent-to-child outcomes, and parent-selection frequencies. $\mathcal{M}_\theta$ summarizes these statistics into factual observations $A_t = \mathcal{M}_\theta(\text{stats}(\mathcal{D}_p))$ without additional interpretation. These observations complete the initial inner-loop context $\tilde{c}_t^0 = (c_t, K_t, A_t)$, which the inner rounds condition on and update.

Iterative query optimization. Let $\mathcal{S}_t^r$ denote the documents retained after inner round r , and $\hat{s}_t(d)$ the predicted evaluator score of a candidate x_{t+1} obtained by improving x_t using document d alone. Starting with $\mathcal{S}_t^0 = \emptyset$ and $K_t^0 = K_t$, each round $r = 1, \dots, R$ performs four operations:

- (1) **Query Construction:** The LLM $\mathcal{M}_\theta$ constructs J queries targeting the remaining knowledge gaps. The query batch is $Q_r = (q_r^{(j)})_{j=1}^J$, with each query sampled as $q_r^{(j)} \sim \mathcal{M}_\theta(\tilde{c}_t^{r-1}, \mathcal{S}_t^{r-1}, \{\hat{s}_t(d)\}_{d \in \mathcal{S}_t^{r-1}})$. At $r = 1$, the document and score inputs are empty, so query construction uses only the initial context $\tilde{c}_t^0$. Later rounds also use the retained documents and their predicted scores.
- (2) **Web Search:** Each distinct query in Q_r is executed once per round. The returned documents are combined with the previously retained documents to form the pool (i.e., local search database in Figure 5) $\mathcal{P}_r = \mathcal{S}_t^{r-1} \cup \text{SEARCH}(Q_r)$.
- (3) **Hypothetical Evidence Scoring:** When unscored documents are available, a single call to $\mathcal{M}_\theta$ predicts $\hat{s}_t(d) = \mathcal{M}_\theta(\tilde{c}_t^{r-1}, \mathcal{E}(x_t), d)$ for each such $d \in \mathcal{P}_r$. These *hypothetical absolute scores* are expressed on the evaluator’s scale and provide a surrogate signal for the inner objective in Eq. 1 (Figure 8a shows the model’s ability to predict these scores). Each document is scored only once within the inner loop, and its score is reused in later rounds.
- (4) **Knowledge State Update:** The same call used for hypothetical evidence scoring also updates the knowledge state to K_t^r using the new documents, yielding the next round’s context $\tilde{c}_t^r = (c_t, K_t^r, A_t)$. If no documents require

Figure 6: Discovery performance of OpenEvolve with and without EVO DUET. Results cover 21 paired tasks with $N = 1$ or 8 candidates per iteration. For each model, method, task, and N , we report the best NDG across four runs. **(a)** Mean best NDG across tasks and the gain from adding EVO DUET (Δ NDG). **(b)** Mean Δ NDG within each task group. **(c)** Task-level Δ NDG versus OpenEvolve’s NDG; black bars and labels show the median gain within each NDG range.

scoring, the call is skipped and $K_t^r = K_t^{r-1}$. The loop then retains up to D documents with the highest predicted scores as $\mathcal{S}_t^r = \text{TopD}_{\hat{s}_t}(\mathcal{P}_r)$.

After all R rounds, the retained Top- D documents $\mathcal{S}_t = \mathcal{S}_t^R$ are passed to the outer loop.

4. Experimental Results

EVO DUET improves discovery, but only for LLMs that can exploit retrieved evidence. At $N = 1$, Figure 6a shows that EVO DUET improves OpenEvolve’s overall NDG from 74.1% to 78.0% (+3.9%) with GPT-5.6-Luna and from 61.3% to 82.3% (+21.0%) with Gemini-3.8-Flash. Qwen3.5-9B, however, shows a 14.4% decline at $N = 1$ and still loses 4.7% with parallel generation at $N = 8$, despite gaining 10.3% when given oracle documents (Figure 3a). Unlike the oracle setting, EVO DUET requires the model to decide when and what to search for based on its own knowledge gaps. This contrast suggests that these additional demands may limit the benefits of retrieval for weaker backbones such as Qwen3.5-9B. Inspection of 50 randomly sampled Qwen3.5-9B revisions with documents at $N = 1$ identifies unused methods in 6% and incorrect implementations in 20% (26% combined; Appendix E.3). These findings suggest that effective bi-level co-evolution depends on the model’s ability to both retrieve and apply relevant evidence.

Parallel generation consistently improves discovery across models. Figure 6a shows that increasing the candidate budget from $N = 1$ to $N = 8$ improves EVO DUET’s overall NDG for all three models. For Qwen3.5-9B, although EVO DUET remains below the corresponding OpenEvolve baseline at both budgets, its overall NDG improves from $N = 1$ to $N = 8$, indicating that parallel generation also benefits this model. We further compare $N \in \{1, 8, 16\}$ for GPT-5.6-Luna and Gemini-3.8-Flash on 8 tasks in Figure 7. We observe that the average NDG increases monotonically with N for both models, rising from 89.6% to 95.7% for GPT-5.6-Luna and from 84.5% to 89.6% for Gemini-3.8-Flash. These results suggest that broader exploration guided by web documents helps LLMs discover better solutions.

EVO DUET achieves its largest average gain in mathematics. As shown in Figure 6b, EVO DUET improves NDG over OpenEvolve on mathematics tasks in five of the six model/budget settings, with an average gain of 7.1% across all six. At $N = 8$, Qwen3.5-9B gains 5.5% despite its negative overall gain, and Gemini-3.8-Flash gains 6.7%.

EVO DUET discovers novel solutions across 11 different tasks. Table 1a shows that EVO DUET surpasses the previous SOTA program scores on eight tasks across five domains and matches them on three more. The mean cost across the eleven reported runs is \$45.56. Interestingly, on Rosetta and Erdős, the model initially evolves solutions, then retrieves public constructions at a later iteration and uses them as starting points for further optimization: refining a published trajectory and locally optimizing a published construction ($C_5 : 0.380859 \rightarrow 0.380859$), respectively. We call this behavior *public artifact reuse*, one of six behaviors reported in Appendix E.1. This behavior occurs in only 6 of 82 GPT-5.6-Luna runs (7.3%), compared with *method transfer* (55 of 82), in which the model applies principles or methods

Figure 7: Scaling effect of N .

Figure 8: Program improvement with web documents and patterns of document use. Results cover 8,200 iterations from 82 GPT-5.6-Luna runs across 21 tasks. (a) Predicted versus evaluated candidate scores, scaled to $[0, 1]$ using each task’s 2nd and 98th percentiles. (b) Rates at which the selected candidate improves on its parent (left axis) or sets a new best score within the run (right axis), grouped by gate decision. Arrows compare **NO-OP** iterations with **RETRIEVE** iterations that retain at least one promising document. (c) Percentage of runs exhibiting each behavior. Each run is counted at most once per category and may appear in multiple categories.

retrieved by searching relevant literature (Figure 8c). Only two of these 11 SOTA results reuse public artifacts in their best programs (in Appendix K).

The largest median gain occurs on partially solved tasks. Figure 6c compares OpenEvolve and EVO DUET across 126 combinations of tasks, models, and candidate counts. When OpenEvolve’s NDG is 5–20%, 20–40%, 40–60%, and 60–80%, the median gains from EVO DUET are -5.4%, +17.5%, +9.2%, and +2.4%, respectively. When OpenEvolve already performs well ($\text{NDG} \geq 80\%$), the median gain is 0.0% across 75 comparisons. Of the 52 comparisons with OpenEvolve $\text{NDG} \geq 95\%$, six show declines greater than 5%. When OpenEvolve makes little progress (NDG below 5%), EVO DUET raises five of the ten cases above 5%, with a median gain of +71.8% among these five. In the remaining five cases, both methods stay near the initial program’s performance. Overall, EVO DUET tends to provide smaller gains when OpenEvolve’s NDG is higher (Pearson $r = -0.41$).

5. Analysis and Discussions

5.1. How Does Web Search Help?

Hypothetical evidence scores track actual program performance. Across 4,324 retrievals, hypothetical evidence scores correlate strongly with the selected candidates’ evaluated scores (Spearman $\rho = +0.86$; Figure 8a). Correlations are positive on all 21 tasks, with a median of +0.74. This supports using these scores as a surrogate signal for inner-loop query optimization (§ 3.4).

Programs improve more often with promising documents. A document is *promising* when its hypothetical evidence score exceeds the parent’s actual evaluator score, i.e., $\hat{s}_t(d) > \mathcal{E}(x_t)$. When **RETRIEVE** retains at least one such document, the selected candidate improves on its parent in 67.1% of iterations and sets a new run best in 14.1%, compared with 52.1% and 9.6% under **NO-OP** (Figure 8b). Under **LOOK-UP**, which reuses stored documents, these rates are 61.2% and 10.1%, respectively. On 17 of 21 tasks, parent improvement rates are higher with promising documents than under **NO-OP** (medians: 69% vs. 54%). However, 36.5% of retrievals yield no promising document; the parent improvement rate in these cases is only 38.3%. These results suggest that hypothetical evidence scoring helps identify documents useful for improving the current solution.

Web documents mainly provide methods and performance targets. Figure 8c summarizes six behavior categories across 82 GPT-5.6-Luna runs (8,200 iterations), with each run counted once in every applicable category. The most common behaviors are applying principles and methods from retrieved documents (55 runs) and using published best scores as reference targets (40 runs). These targets guide program development, while the task evaluator measures the resulting programs’ performance. We also observe reuse of published solutions (6 runs) and unsuccessful revisions inspired by retrieved ideas (29 runs). Detailed explanations are presented in Appendix E.1.

Acknowledgments

This work was partly supported by the IITP grants (RS-2022-II220077, RS-2022-II220113, RS-2022-II220959, RS-2022-II220871) funded by the Korea government (MSIT) and the BK21 FOUR program, SNU in 2025. This research was supported by the “Advanced GPU Utilization Support Program” funded by the Government of the Republic of Korea (Ministry of Science and ICT).

AI use statement

In this work, we used generative AI tools for trajectory analysis. We have not used generative AI tools for idea proposal or method development, and proof-related tasks are not applicable to this work. Additionally, we used generative AI tools for paper writing and figure preparation. We also used generative AI tools to retrieve and summarize oracle documents, as described in Appendix C.2.

We have reviewed all AI-assisted work. We checked the AI-assisted text and figures for consistency with the reported experimental results. For trajectory analysis, we checked the interpretations against recorded search queries, retrieved documents, parent and child programs, and evaluator outputs, with worked cases provided in Appendix I. We also inspected cases of public artifact reuse and documented the sources of reused solutions, as detailed in Appendices E.1 and K.

We take responsibility for the final content of this work, including text, claims or artifacts produced with the aid of generative AI.

Ethics statement

This work evaluates LLM-guided computational optimization across a set of tasks, using publicly available web sources to inform the search. To support proper attribution, we document cases of public artifact reuse, including the original sources and subsequent optimization steps, in Appendices E.1 and K. The reported gains reflect performance under the task evaluators used in this study. The resulting programs require independent validation before use in other settings. Appendix H discusses source attribution, the reliability of retrieved information, program validation, and human oversight of downstream applications.

Reproducibility statement

We describe EVO DUET in Section 3 and provide pseudocode, inference settings, and retrieval budgets in Appendix B. Task definitions, evaluation procedures, and oracle-document construction are documented in Appendix C, and the prompt templates are provided in Appendix J. Detailed experimental results appear in Appendix D. Appendix I links selected search trajectories to retrieved sources, code revisions, and evaluation results. Appendix K provides complete source listings and identifies the runs underlying Table 1a. Detailed trajectories, prompt templates, and complete program listings are provided in the supplementary materials (Appendices I–K).

A. Extended Related Work

Evolving solutions and search strategies. LLM-driven discovery methods differ in whether they optimize candidate programs, search procedures, prompts, or model parameters. FunSearch (Romera-Paredes et al., 2024), AlphaEvolve (Novikov et al., 2025), OpenEvolve (Sharma, 2025), and CodeEvolve (Assumpção et al., 2025) use execution feedback to evolve programs. EoH (Liu et al., 2024) jointly evolves heuristic descriptions and code. At the search level, ShinkaEvolve (Lange et al., 2025), PACEvolve (Yan et al., 2026), and AdaEvolve (Cemri et al., 2026) adapt selection, context management, and exploration, respectively, while EvoX (Liu et al., 2026a) jointly evolves solutions and search strategies. The Darwin Gödel Machine (Zhang et al., 2025), Hyperagents (Zhang et al., 2026), and Meta-Harness (Lee et al., 2026e) optimize agent or harness code. CORAL (Qu et al., 2026) coordinates collaborative evolution through shared memory, and SkyDiscover (Liu et al., 2026b) provides modular discovery infrastructure. OPRO (Yang et al., 2023), APO (Pryzant et al., 2023), TextGrad (Yuksekgonul et al., 2024), and GEPA (Agrawal et al., 2025) optimize prompts or textual variables using performance feedback or textual critiques. ThetaEvolve (Wang et al., 2025) and TTT-Discover (Yuksekgonul et al., 2026) update model parameters through reinforcement learning during search, while Kernel-Smith (Du et al., 2026) and Evolution Fine-Tuning (Lee et al., 2026f) train on evolutionary trajectories.

Web-augmented scientific discovery. DeepEvolve (Liu et al., 2025) sequentially couples deep research with program revision and evaluation, using prior evaluation outcomes to guide subsequent research. KernelEvolve (Liao et al., 2025) uses runtime diagnostics to guide retrieval for kernel optimization. AI co-scientist (Gottweis et al., 2025) integrates literature search into hypothesis generation and scientific review. Robin (Ghareeb et al., 2026) uses literature search to propose and assess candidate hypotheses, then incorporates experimental feedback into subsequent refinement. The AI Scientist (Lu et al., 2026), AI-Researcher (Tang et al., 2025), and Agent Laboratory (Schmidgall et al., 2025) connect literature search, computational experiments, and reporting. AgentRxiv (Schmidgall & Moor, 2025) and AgenticSciML (Jiang & Karniadakis, 2026) reuse accumulated research reports or method memories. Coscientist (Boiko et al., 2023), ChemCrow (Bran et al., 2024), and Biomni (Huang et al., 2026) combine external information with scientific tools.

Retrieval control and query refinement. Retrieval methods address when to search and how to refine queries. ReAct (Yao et al., 2023), IRCot (Trivedi et al., 2023), Iter-RetGen (Shao et al., 2023), and Auto-RAG (Yu et al., 2024) guide successive retrieval steps using intermediate reasoning, answers, or observations. Self-RAG (Asai et al., 2023), FLARE (Jiang et al., 2023), Adaptive-RAG (Jeong et al., 2024), and CRAG (Yan et al., 2024) base retrieval decisions on reflection, uncertainty, question complexity, and evidence quality, respectively. Rewrite-Retrieve-Read (Ma et al., 2023) learns query reformulation, while RQ-RAG (Chan et al., 2024) learns rewriting, decomposition, and disambiguation. Search-R1 (Jin et al., 2025), R1-Searcher (Song et al., 2025), and ReSearch (Chen et al., 2025) learn search policies from outcome rewards. REPLUG (Shi et al., 2024) uses feedback from a frozen LM to train a retriever, while ITER (Chen et al., 2026) trains a retriever conditioned on reasoning and search histories. EVODUET couples solution and query evolution through a shared task objective. Its knowledge-state gate chooses whether to retrieve new documents, reuse stored documents, or skip retrieval. The inner loop selects evidence using predicted candidate scores and refines queries without generating or evaluating programs. The outer loop records measured outcomes to inform subsequent retrieval decisions. Model parameters and prompt templates remain fixed throughout.

B. Method Details

Algorithm 1 presents the overall EVODUET procedure, and Algorithm 2 details its query optimization loop. The inner loop refines queries using predicted candidate scores; the outer loop evaluates solutions and records their actual scores. All model calls use the same frozen $\mathcal{M}_\theta$.

B.1. Outer Loop: Solution Optimization

Candidate generation and selection. The gate sets $N_t = 1$ for `NO-OP` and $N_t = N$ for `LOOK-UP` or `RETRIEVE`, including retrievals that return no usable documents. Candidates are sampled independently in parallel from the same prompt (I, c_t, S_t) and evaluated after successful generation and parsing. Only the best valid candidate under the task’s optimization direction is passed to ϕ ; ties favor the earlier candidate. If all candidates fail, the scaffold applies its existing retry policy.

Algorithm 1 EVODUET: overall procedure.

Input: Task $(I, x_0, \mathcal{E})$, selection policy ϕ , outer iterations T

Input: Candidate count N , retrieval settings (R, J, M, D, K)

```
1:  $\mathcal{D}_e \leftarrow \{(x_0, \mathcal{E}(x_0))\}$ ;  $\mathcal{D}_s \leftarrow \emptyset$ 
2: for  $t = 0, \dots, T - 1$  do ▷ Outer loop: solution optimization
3:    $(x_t, \mathcal{H}_t) \sim \phi(\mathcal{D}_e)$ ;  $c_t \leftarrow [\mathcal{H}_t; x_t]$ 
4:    $(K_t, g_t) \leftarrow \text{GATE}_{\mathcal{M}_\theta}(c_t, \mathcal{D}_s)$  ▷ Retrieval gating
5:    $\mathcal{S}_t \leftarrow \emptyset$  ▷ NO-OP uses no documents
6:   if  $g_t = \text{LOOK-UP}$  then
7:      $\mathcal{S}_t \leftarrow$  stored documents identified by the gate
8:   else if  $g_t = \text{RETRIEVE}$  then ▷ Inner loop: query optimization
9:      $\mathcal{S}_t \leftarrow \text{OPTIMIZEQUERIES}(c_t, K_t, \mathcal{D}_e, \mathcal{E}(x_t))$ 
10:  end if
11:   $N_t \leftarrow N$  if  $g_t \in \{\text{LOOK-UP}, \text{RETRIEVE}\}$ , otherwise 1
12:  Generate  $x_{t+1}^{(n)} \sim \mathcal{M}_\theta(I, c_t, \mathcal{S}_t)$ ,  $n = 1, \dots, N_t$ , in parallel
13:  Evaluate candidates with  $\mathcal{E}$  and collect valid candidates in  $\mathcal{C}_t^{\text{valid}}$ 
14:  if  $\mathcal{C}_t^{\text{valid}} \neq \emptyset$  then
15:     $x_{t+1} \leftarrow \arg \text{opt}_{x \in \mathcal{C}_t^{\text{valid}}} \mathcal{E}(x)$ 
16:     $\mathcal{D}_e \leftarrow \phi(\mathcal{D}_e \cup \{(x_{t+1}, \mathcal{E}(x_{t+1}))\})$ 
17:    Update  $\mathcal{D}_s$  with evidence and the measured outcome if  $g_t \neq \text{NO-OP}$ 
18:  else
19:    Apply the scaffold's retry policy
20:  end if
21: end for
22: return best evaluated solution
```

Search database update. The search database $\mathcal{D}_s$ associates the selected candidate's outcome with the documents it received. A record contains the executed queries, retained documents and their predicted scores, document identifiers, actual parent and candidate scores $\mathcal{E}(x_t)$ and $\mathcal{E}(x_{t+1})$, and evaluator feedback. Each prediction assumes one document alone, whereas the candidate uses the retained set jointly; the measured outcome therefore belongs to that complete attempt. Intermediate rounds receive no separate measured outcome. Failed evaluations leave the outcome unknown. Candidate code, responses, evaluations, and intermediate retrieval results are retained in the iteration trace.

B.2. Knowledge-Gap-Based Retrieval Gating

Gate inputs and outputs. A single call reads the parent solution, the scaffold's evolutionary history, and recent search records. It returns the knowledge state K_t , a decision g_t , and document identifiers when $g_t = \text{LOOK-UP}$. The knowledge state distinguishes prior model knowledge, findings from searches and evaluations, and unresolved questions about the current solution. The gate runs before population analysis, so **NO-OP** and **LOOK-UP** require no additional analysis call.

Stored search context. The gate, query construction, and evidence scoring share a snapshot of the ten most recent records in $\mathcal{D}_s$, fixed throughout the outer iteration. Each record shows its queries, retained predictions, document identifiers, and measured outcomes, with up to three document bodies. Bodies are truncated to 10,000 characters, preferring full text over a snippet when available. This context lets the model relate previously retrieved evidence to actual optimization outcomes.

No-op and look-up. Under **NO-OP**, the solution prompt receives $\mathcal{S}_t = \emptyset$. Under **LOOK-UP**, the gate selects stored document identifiers, and their bodies are added to the solution prompt. Both decisions bypass the inner loop and make no web-search call.

B.3. Inner Loop: Query Optimization

Algorithm 2 is invoked only under **RETRIEVE** and returns the documents used for solution generation.

Population state descriptor. After a **RETRIEVE** decision, deterministic statistics summarize the retained population $\mathcal{D}_p$ in $\mathcal{D}_e$: its score distribution, recent parent-to-child outcomes, and parent-selection frequencies. Following EvoX,

Algorithm 2 Inner loop: query optimization.

Input: R rounds, J queries per round, M documents per query, local pool capacity D

```
1: function OPTIMIZEQUERIES( $c_t, K_t, \mathcal{D}_e, \mathcal{E}(x_t)$ )
2:    $\mathcal{D}_p \leftarrow$  retained solutions in  $\mathcal{D}_e$ ;  $A_t \leftarrow \mathcal{M}_\theta(\text{stats}(\mathcal{D}_p))$ 
3:    $K_t^0 \leftarrow K_t$ ;  $\mathcal{S}_t^0 \leftarrow \emptyset$ ; initialize an empty score cache  $\hat{s}_t$ 
4:    $\tilde{c}_t^0 \leftarrow (c_t, K_t^0, A_t)$ 
5:   for  $r = 1, \dots, R$  do
6:      $q_r^{(j)} \sim \mathcal{M}_\theta(\tilde{c}_t^{r-1}, \mathcal{S}_t^{r-1}, \{\hat{s}_t(d)\}_{d \in \mathcal{S}_t^{r-1}})$ ,  $j = 1, \dots, J$ , in parallel
7:      $Q_r \leftarrow (q_r^{(j)})_{j=1}^J$  ▷ Query construction
8:      $\mathcal{W}_r \leftarrow \text{SEARCH}(Q_r)$  ▷ Up to  $M$  documents per distinct query
9:      $\mathcal{P}_r \leftarrow \text{DEDUPLICATE}(\mathcal{S}_t^{r-1} \cup \mathcal{W}_r)$ 
10:     $\mathcal{U}_r \leftarrow \{d \in \mathcal{P}_r : \hat{s}_t(d) \text{ is undefined}\}$ 
11:     $K_t^r \leftarrow K_t^{r-1}$ 
12:    if  $\mathcal{U}_r \neq \emptyset$  then ▷ Evidence scoring and knowledge update
13:       $\{\hat{s}_t(d)\}_{d \in \mathcal{U}_r}, K_t^r \leftarrow \text{PREDICT}_{\mathcal{M}_\theta}(\tilde{c}_t^{r-1}, \mathcal{E}(x_t), \mathcal{P}_r)$ 
14:      Cache validated predictions; preserve previously cached scores
15:    end if
16:     $\mathcal{S}_t^r \leftarrow \text{TopD}_{\hat{s}_t}(\mathcal{P}_r)$  ▷ Rank documents with validated scores
17:     $\tilde{c}_t^r \leftarrow (c_t, K_t^r, A_t)$ 
18:  end for
19:  return  $\mathcal{S}_t^R$  ▷ Pass retained documents to the solution prompt
20: end function
```

$\mathcal{M}_\theta$ converts these statistics into factual observations A_t without additional interpretation. The call is skipped if the population is empty. The parent, its score, the evolutionary history, and A_t remain fixed across all R inner rounds.

Query construction. Each round generates J independent responses to the same query prompt in parallel. A response contains one query, its keywords, target source type, intended discovery direction, and rationale; the query text is limited to 500 characters. Round 1 uses $\tilde{c}_t^0 = (c_t, K_t, A_t)$. Later rounds additionally receive the retained documents and their predicted scores, and use the updated knowledge state K_t^{r-1} to target the remaining gaps.

Web search and document pooling. Queries that differ only in whitespace are executed once per round. Each distinct valid query is sent to Tavily with advanced search depth and returns up to M documents. The results are merged with $\mathcal{S}_t^{r-1}$ and deduplicated using the URL or provider identifier, title, and raw body. The pool $\mathcal{P}_r$ therefore contains at most JM documents in the first round and $D + JM$ thereafter. A discarded document re-enters the pool only if a later search returns it again.

Hypothetical evidence scoring and knowledge update. When unscored documents are present, one model call predicts their absolute candidate scores $\hat{s}_t(d)$ on the evaluator’s scale and updates the knowledge state. Each prediction estimates the score obtained by improving the fixed parent using document d alone. Validated predictions are cached for the current inner loop and reused if the document appears again. Up to D documents with the best predicted scores are retained, with ties resolved in pool order. If no document needs scoring, the call is skipped and $K_t^r = K_t^{r-1}$. After round R , the final local pool of up to D documents is passed to the outer loop. Their bodies, titles, and URLs enter the solution prompt without a separate summarization call.

Validation and failures. Only finite predictions for valid, previously unscored document identifiers enter the ranking; existing predictions cannot be overwritten. A complete valid response updates the knowledge state. Partial responses retain valid predictions while preserving the previous knowledge state, and a failed scoring call preserves both the previous retained set and state. Failed searches consume their attempts, and malformed query samples are not replaced. All R rounds run without early stopping. If no usable evidence is retained, the outer loop receives $\mathcal{S}_t = \emptyset$.

B.4. Inference Settings and Call Budget

Settings. The default retrieval budget is $R = 3$ rounds, $J = 1$ query per round, $M = 5$ documents per query, and $D = 3$ documents retained in the local pool. The entire final local pool enters the solution prompt. We evaluate $N = 1$ and $N = 8$ for candidate generation. All model calls use temperature 0.7, top- p 0.95, medium reasoning effort, and up

to 32,768 output tokens. Gate, query, and evidence-scoring calls use user-only prompts with tools disabled. Population analysis uses EvoX’s system prompt and supplies the deterministic statistics in the user message.

Per-iteration budget. The following counts exclude retries. Under [RETRIEVE](#), the model-call budget includes one gate, at most one population analysis, RJ query constructions, and up to R evidence-scoring calls. With the default settings, the limits are eight retrieval-related model calls and three web searches. Candidate generation and evaluation follow separately.

Decision	Retrieval LLM calls	Web searches	Generations
NO-OP	1	0	1
LOOK-UP	1	0	N
RETRIEVE	$\leq RJ + R + 2$	$\leq RJ$	N

B.5. Coupling Web Search with Solution Evolution

Figure 9 compares three ways to integrate web search into OpenEvolve: joint-level retrieval (Table 2), sequential retrieval as in DeepEvolve (Liu et al., 2025), and bi-level retrieval in EVODUET. They differ in when they search, what guides their queries, and how they reuse search results.

Figure 9: Three ways to couple web search with solution evolution. *Top:* search runs within generation (joint-level), precedes generation (sequential), or co-evolves with solutions (bi-level). Blue denotes search, violet solution evolution, and amber the knowledge-gap gate; the dashed overlap marks the coupling between the two loops. *Bottom:* search timing, query guidance, and memory for reuse across iterations. Checkmarks highlight EVODUET’s design choices.

Search placement changes how evidence enters the solution loop. *Joint-level* retrieval runs during program generation: the LLM writes queries alongside program edits and must call Tavily at least once per iteration, with up to three tool rounds. *Sequential* retrieval, as in DeepEvolve, runs a deep-research agent before generation at every iteration. Given the current program and programs selected as inspiration, the agent plans research questions, searches the web, and writes a proposal. Reflection can revisit planning or search when it judges the report incomplete; a coding agent then implements the proposal, followed by debugging and evaluation. Both joint-level and sequential retrieval are single-level: neither scores queries or documents against the task objective.

EVODUET couples query and solution evolution through a knowledge-gap gate (§ 3). The gate reads the current knowledge state and selects [RETRIEVE](#), [LOOK-UP](#), or [NO-OP](#). Under [RETRIEVE](#), the inner loop refines queries over R rounds and selects documents using predicted program scores. The outer loop generates and evaluates programs, then stores the documents and measured outcomes in the search database to guide later gate decisions and queries.

Table 2: Joint-level versus bi-level retrieval (NDG, %).

Method	Denoising	Sums/Diffs
No search	0.0%	14.8%
Joint-level	43.2%	42.9%
Bi-level	84.5%	76.0%

Joint-level search repeatedly returns the same pages on Denoising. In the GPT-5.6-Luna trajectory analyzed in Section 2.3, joint-level retrieval returns 85 distinct URLs versus 248 for EVODUET; 88.1% of its returned URLs are repeats. Across eligible four runs, mean NDG at iteration 100 is 43.2% on Denoising and 42.9% on Sums/Diffs, compared with 84.5% and 76.0% for EVODUET (Table 2).

The DeepEvolve comparison uses published results. On Molecule and Burgers, DeepEvolve’s released scores are 0.8149 and 0.6666, respectively, below our OpenEvolve baseline (0.8496 and 0.6937); EVODUET reaches 0.8524 and 0.7846 (Table 1c). The local scores are the best across available four runs with GPT-5.6-Luna at iteration 100; DeepEvolve was not rerun with the same model or search budget.

C. Experimental Setup Details

We evaluate on 31 tasks in two collections (Table 3). The descriptions below specify each task’s optimization variables, constraints, and evaluation procedure. Arrows indicate whether lower ($\downarrow$) or higher ($\uparrow$) values are better. Unless stated otherwise, we report the evaluator’s native objective.

Table 3: Task coverage.

Domain	Tasks	#
Simple Scientific Optimization	Pressure Vessel, SINDy, Batch Reactor, LABS-27, LJ-13, Chwirut2, Perovskites, SRSD, GuacaMol, Summit	10

Total		31

C.1. Task Descriptions

C.1.1. Simple Scientific Optimization

This collection consists of ten tasks constructed from public sources. For each task, an oracle document was retrieved when the task was created (Appendix C.2). We describe the optimization problem and report the scores of both the initial program and the solution stated in the oracle document.

Pressure Vessel Design (Yang et al., 2013) ($\downarrow$ cost)

The program specifies a vessel by its shell thickness d_s , head thickness d_h , inner radius r , and length L . The two thicknesses must be multiples of 0.0625 in, and the length is restricted to $L \leq 200$ in. The objective is to minimize the fabrication cost

$$C(d_s, d_h, r, L) = 0.6224d_s r L + 1.7781d_h r^2 + 3.1661d_s^2 L + 19.84d_s^2 r,$$

subject to the evaluator’s thickness, volume, and dimension constraints. The initial program has a cost of 10,905.34. The oracle solution, taken from a SlideShare derivation of the optimum, has a cost of 6,059.71.

SINDy Cubic 2D (Brunton et al., 2016) (↓ NRMSE)

The input consists of 2,500 samples from a two-dimensional trajectory. The program returns the coefficients of a polynomial vector field $\dot{\mathbf{x}} = f(\mathbf{x})$ of degree at most three. The evaluator measures how accurately the recovered field describes the dynamics and how accurately its integrated trajectory reproduces the reference trajectory. The objective is to minimize the mean of the vector-field and trajectory normalized root mean squared errors (NRMSEs).

The initial program’s field and trajectory NRMSEs are 0.670 and 1.197, respectively. The cubic-oscillator equation in the PySINDy oracle document gives corresponding errors of approximately zero and 1.7×10^{-8} .

Batch Reactor Control (APMonitor, 2025) (↑ $B(1)$)

The program controls the temperature of a batch reactor with consecutive reactions $A \rightarrow B \rightarrow C$. It returns a schedule of 501 temperature values over $t \in [0, 1]$, each constrained to $[298, 398]$ K. The evaluator integrates the reaction kinetics under this schedule, and the objective is to maximize the terminal concentration $B(1)$ of the intermediate product. The initial constant-temperature policy, $T(t) \equiv 350$ K, achieves 0.57706. The APMonitor GEKKO solution supplied by the oracle achieves 0.61076.

LABS-27 (Packebusch & Mertens, 2016) (↓ energy)

The low-autocorrelation binary sequence problem asks for a sequence $s = (s_1, \dots, s_{27}) \in \{-1, +1\}^{27}$ with small correlations at nonzero shifts. Its aperiodic autocorrelation at lag k and its energy are

$$C_k(s) = \sum_{i=1}^{27-k} s_i s_{i+k}, \quad E(s) = \sum_{k=1}^{26} C_k(s)^2.$$

The program returns the sequence, and the objective is to minimize $E(s)$. The initial sequence has energy 177. The run-length-encoded optimum reported by Packebusch and Mertens in the oracle document has energy 37.

Lennard–Jones-13 (Cambridge Cluster Database, n.d.) (↓ energy)

The program returns the positions $\mathbf{x}_1, \dots, \mathbf{x}_{13}$ of 13 atoms in three-dimensional space. Writing $r_{ij} = \|\mathbf{x}_i - \mathbf{x}_j\|_2$, the objective is to minimize the reduced Lennard–Jones energy

$$E(\mathbf{x}_1, \dots, \mathbf{x}_{13}) = 4 \sum_{1 \leq i < j \leq 13} (r_{ij}^{-12} - r_{ij}^{-6}).$$

Coincident atoms are invalid. The initial straight-chain configuration has energy -12.374 , while the configuration supplied by the Cambridge Cluster Database oracle has energy -44.327 .

NIST Chwirut2 (National Institute of Standards and Technology, n.d.) (↓ RSS)

Given NIST’s 54 observations (x_i, y_i) , the program estimates the three parameters of the nonlinear regression model $\hat{y}(x; b) = e^{-b_1 x} / (b_2 + b_3 x)$. The objective is to minimize the residual sum of squares

$$\text{RSS}(b) = \sum_{i=1}^{54} \left(y_i - \frac{e^{-b_1 x_i}}{b_2 + b_3 x_i} \right)^2.$$

The initial program uses NIST Start 1 and has an RSS of 14,794.79. The NIST-certified parameters in the oracle document give an RSS of 513.048.

OLYMPUS Perovskites (Häse et al., 2021a;b) (↓ bandgap)

The search space contains 192 compositions, each specified by an organic component, a cation, and a halide. The program selects one composition, and the evaluator returns its published HSE06 bandgap from the dataset. The objective is to minimize this bandgap. The initial composition has a bandgap of 5.3704 eV. The hydrazinium–Sn–I composition identified in the Gryffin tutorial oracle has a bandgap of 1.5249 eV.

SRSD Feynman I.27.6 (Matsubara et al., 2024) ($\downarrow$ error)

The program returns a symbolic expression that predicts the focal distance from the three inputs (d_1, n, d_2) . We use the official split of 8,000 training, 1,000 validation, and 1,000 test examples. The optimization objective is the mean squared relative error on the validation set. The initial expression has an error of 0.905. Equation 27.6 of the Feynman Lectures, supplied by the oracle, gives zero error.

GuacaMol C₁₁H₂₄ (Brown et al., 2019) ($\uparrow$ score)

The program proposes molecular structures as SMILES strings, with C₁₁H₂₄ as the target molecular formula. The evaluator canonicalizes and deduplicates the proposals, then averages their formula-agreement scores over the top 159 structures. Missing structures contribute zero, so the objective rewards a collection of distinct matching structures. The initial program supplies 5 of the 159 structures and scores 0.0315. The PubChem isomer list supplied by the oracle gives a score of 1.0.

Summit Baumgartner (Felton et al., 2021; Baumgartner et al., 2019) ($\uparrow$ yield)

The program specifies reaction conditions for an aniline C–N coupling: catalyst, base, base loading, temperature, and residence time. Five released emulators predict the yield under these conditions. Each prediction is clipped to $[0, 1]$, and the objective is to maximize their mean. The initial conditions score 0.655. The conditions in a row of the released dataset, identified by the oracle, score 1.0.

C.1.2. SIMPLETES

We use 21 tasks from SIMPLETES (WILL Team, 2026), together with their released initial programs and evaluators. For each task, the released best program or construction is re-evaluated with the same evaluator and serves as the SOTA anchor for NDG. The tasks cover the six domains below.

Quantum compilation. Swap Reduction searches over initial qubit mappings and routing decisions.

Swap Reduction ($\downarrow$ SWAPs)

Given a logical circuit and a device connectivity graph, a Rust routing policy chooses the initial assignment of logical qubits to physical qubits and inserts SWAP operations as the circuit is processed. The resulting mapping must allow each two-qubit gate to execute on a hardware edge. The optimization target is to reduce the number of inserted SWAPs.

The evaluation scaffold contains 72 circuit–device cases across three topologies. Its native score measures the CNOT overhead saved relative to reference routings. In the paper, we report the number of added SWAPs on the 24 circuits assigned to the 20-qubit device.

Astrodynamics. Each program returns a spacecraft trajectory as a sequence of launch, flyby, deep-space maneuver, and arrival events, with an epoch and a state for each event. The evaluator checks the trajectory using DE430 ephemerides and two-body propagation, enforces the task’s time windows and minimum flyby altitudes, and charges any speed mismatch at a flyby. The common objective is to minimize the total velocity-change budget, in km/s,

$$\Delta v_{\text{total}} = \Delta v_{\text{launch}} + \Delta v_{\text{flybys}} + \Delta v_{\text{maneuvers}} + \Delta v_{\text{arrival}}.$$

The five tasks differ in their destinations, permitted flyby bodies, and arrival conditions.

Cassini ($\downarrow \Delta v$)

The trajectory begins at Earth and ends with capture into a 115-day orbit around Saturn. Flybys may use Venus, Earth, Mars, or Jupiter. A feasible trajectory may contain at most six flybys and six deep-space maneuvers.

Galileo ($\downarrow \Delta v$)

The trajectory begins at Earth and ends with capture into a 210-day orbit around Jupiter. Venus and Earth are the permitted flyby bodies, and the trajectory is limited to five flybys and five deep-space maneuvers.

Mariner 10 ($\downarrow \Delta v$)

The trajectory travels from Earth to Mercury, with Venus as the only permitted flyby body. The arrival contribution to Δv is zero when the arrival speed relative to Mercury is below 10 km/s.

Rosetta ($\downarrow \Delta v$)

The trajectory travels from Earth to a rendezvous with comet 67P at a fixed arrival epoch. Flybys may use Earth or Mars, and each flyby must maintain an altitude of at least 300 km.

Voyager 2 ($\downarrow \Delta v$)

The trajectory travels from Earth to a Neptune flyby, with intermediate flybys permitted at Jupiter, Saturn, and Uranus. The arrival contribution to Δv is zero when the arrival speed relative to Neptune is below 30 km/s.

Scientific algorithms. These tasks evaluate algorithms for statistical estimation. Single-Cell RNA-seq Denoising maximizes reconstruction quality.

Single-Cell RNA-seq Denoising ($\uparrow$ score)

The input is a matrix of noisy unique molecular identifier (UMI) counts. The program returns a denoised matrix of the same shape. For each dataset, the evaluator averages a normalized mean-squared-error score and a normalized Poisson score, with the additional requirement that the Poisson score be at least 0.97. The objective is to maximize this combined score. Program search uses the Pancreas dataset, while the reported result is the mean score on the held-out PBMC and Tabula datasets.

AI foundations. Each task asks the program to define a parametric predictive law and a routine for fitting it. The law is fitted separately for each evaluation group, subject to a task-specific parameter budget. Search is guided by training R^2 , whereas the paper reports held-out R^2 , clipped to $[-1, 1]$. The tasks differ in their input variables, prediction targets, and held-out regimes.

Domain Mixture ($\uparrow R^2$)

The law predicts losses on five domains from the proportions of those domains in a training mixture. Evaluation covers four model sizes, with at most 35 fitted parameters per size. The test set contains 24 unseen mixtures, measuring how well the fitted law predicts losses for mixtures absent from training.

U Shape ($\uparrow R^2$)

The law predicts Brier score as a function of log compute on nine benchmarks. Each benchmark permits at most six fitted parameters. The held-out set contains 127 observations at higher compute, so the reported score measures extrapolation beyond the training regime.

LR & BSZ ($\uparrow R^2$)

The law predicts language-model loss from learning rate, batch size, data size, and model parameter count, using at most 26 fitted parameters. The test set contains 117 runs at a model size and data budget absent from training, assessing transfer of the fitted relationship to that held-out setting.

Parallel ($\uparrow R^2$)

The law predicts loss from model parameter count and the number P of parallel streams. It is fitted on two datasets, with at most four parameters per dataset. Training uses observations with $P \leq 4$, and evaluation uses $P = 8$, testing extrapolation to a larger number of streams.

Algorithm engineering. We use two AtCoder Heuristic Contest problems from ALE-Bench (Imajuku et al., 2025). For each task, a C++ solver is evaluated on 150 public inputs with a 2 s limit per case. A run receives the sum of the official case scores, or zero if any case fails. The reported task score is the average over four runs.

AHC039: Purse Seine Fishing (↑ score)

Given the positions of mackerels and sardines, the solver returns an axis-parallel polygon describing a fishing region. The polygon may have at most 1,000 vertices and a perimeter of at most 4×10^5 . The objective is to maximize the official score by enclosing as many mackerels and as few sardines as possible. We use ALE-Agent’s fifth-place solution as the initial program.

AHC058: Apple Incremental Game (↑ score)

The solver chooses a sequence of machine-upgrade decisions over 500 turns. On each turn, it may perform one upgrade or take no action. If S is the final apple count, the objective is to maximize the official score

$$\text{round}(10^5 \log_2 S).$$

The initial program performs no upgrades and receives a score of zero.

Mathematics. These tasks search for finite representations of mathematical constructions: step functions, circle packings, sign matrices, and integer sets. Each evaluator checks the construction and computes the objective defined below. Circle Packing at $n = 26$ and $n = 32$ constitutes two separate tasks.

Erdős Minimum Overlap (↓ C_5)

The program specifies a step function $h : [0, 2] \rightarrow [0, 1]$ satisfying

$$\int_0^2 h(x) dx = 1.$$

For this function, the evaluator computes C_5 , the maximum overlap between h and its shifted complement. The objective is to minimize C_5 while maintaining the range and integral constraints.

First Autocorrelation Inequality, AC1 (↓ C_1)

The program represents a nonnegative step function on $[-1/4, 1/4]$ by n heights $h_1, \dots, h_n$. Writing $(h * h)_k$ for the discrete convolution of the height sequence with itself, the objective is

$$\min_h C_1(h), \quad C_1(h) = \frac{2n \max_k (h * h)_k}{(\sum_{i=1}^n h_i)^2}.$$

The heights must have a positive sum so that the normalized objective is defined.

Second Autocorrelation Inequality, AC2 (↑ R_2)

The program specifies a nonzero, nonnegative step function f supported on $[-1/4, 1/4]$. Let $f * f$ denote its self-convolution. The objective is to maximize

$$R_2(f) = \frac{\|f * f\|_2^2}{\|f * f\|_1 \|f * f\|_\infty}.$$

Third Autocorrelation Inequality, AC3 (↓ C_3)

The program represents a step function f on $[-1/4, 1/4]$ using signed heights $h_1, \dots, h_n$. The objective is to minimize

$$C_3(f) = \frac{\|f * f\|_\infty}{(f f)^2}, \quad C_3(h) = \frac{2n \max_k |(h * h)_k|}{(\sum_{i=1}^n h_i)^2}.$$

The second expression is the evaluator’s form for the step-height representation. Heights may be positive or negative, but their sum must be nonzero for the objective to be defined.

Circle Packing, $n=26$ and 32 ($\uparrow \sum_i r_i$)

For each of the two values of n , the program returns centers $\mathbf{c}_i = (x_i, y_i)$ and nonnegative radii r_i for n circles. Each circle must lie inside the unit square, and no two circles may overlap:

$$\begin{aligned} r_i &\leq x_i \leq 1 - r_i, & r_i &\leq y_i \leq 1 - r_i, \\ \|\mathbf{c}_i - \mathbf{c}_j\|_2 &\geq r_i + r_j & (i &\neq j). \end{aligned}$$

The objective is to maximize $\sum_{i=1}^n r_i$. The evaluator checks the geometric constraints with tolerance 10^{-12} .

Hadamard, Order 29 ($\uparrow$ ratio)

The program returns a matrix $H \in \{-1, +1\}^{29 \times 29}$. The objective is to maximize $|\det H|$. The evaluator computes the determinant exactly and reports its absolute value divided by a fixed normalization constant.

Sums and Differences ($\uparrow c$)

The program returns a set A containing between 2 and 512 distinct integers in $[-10^6, 10^6]$. Define its sumset and difference set as $A + A = \{a + b : a, b \in A\}$ and $A - A = \{a - b : a, b \in A\}$. The objective is to maximize

$$c(A) = \frac{\log(|A + A|/|A|)}{\log(|A - A|/|A|)}.$$

The evaluator computes both sets from the submitted integers and scores their cardinalities through this ratio.

C.2. Oracle Document Construction

SIMPLETES. For each task, we give Claude Code (Claude Opus 5 with maximum reasoning effort, restricted to its WebSearch and WebFetch tools) the task instructions, the initial program, the evaluator, and the best program released by SimpleTES. It identifies the functional differences that let the best program score higher, writes a web-search query for each, and returns the documents it fetched, each with a summary limited to what the document states. The resulting oracle documents are semantic rather than verbatim. Although the prompt asks for each document’s text as fetched, Claude Code’s WebFetch returns the output of a smaller model that reads the page rather than the page itself, so a document carries what its source says about an improvement, such as a method, a formula, or a parameter setting, but not necessarily its wording or its full content.

Simple Scientific Optimization. The oracle documents of these ten tasks were collected with Claude Code when the tasks were created. Each states the task’s solution directly, for example NIST’s certified parameters for Chwirut2 or the Cambridge Cluster Database coordinates for Lennard–Jones-13, and we validate the stated solution with the task’s evaluator; the boxes in Appendix C.1 give its score.

D. Additional Experimental Results

D.1. OpenEvolve with and without Oracle Documents

Table 4 reports the per-task mean and best NDG for the runs underlying Figure 3. We evaluate simple scientific optimization tasks at iteration 20 and the remaining tasks at iteration 100. Each condition reports the mean and maximum NDG over its available runs independently.

D.2. OpenEvolve with and without Parallel Generation

Parallel generation yields larger gains with oracle documents for GPT-5.6-Luna, but without them for Qwen3.5-9B (Table 5). Increasing N from 1 to 8 raises average NDG by 15.0% with oracle documents and 9.8% without on the nine GPT-5.6-Luna tasks; the corresponding gains on the 12 Qwen3.5-9B tasks are 2.2% and 11.8%.

Table 4: Full results for OpenEvolve with and without oracle documents. Entries report **Mean $\pm$ Std / Best** NDG (%; higher is better) over four runs, where Std is the sample standard deviation and Best is the maximum run NDG. Δ reports oracle minus OpenEvolve for Mean / Best, computed before rounding. Bold marks the higher value for each statistic at the displayed precision. Row colors distinguish task groups. The overall row averages task means and task bests across all 31 tasks.

D.3. Inner-loop Budget Ablations

Table 6: Inner-loop budget ablations with GPT-5.6-Luna.

(a) Rounds R on Denoising.		(b) Queries J on Denoising.	
Setting	NDG (%)	Setting	NDG (%)
$R = 1$	58.35%	$J = 1$ (default)	81.77%
$R = 3$ (default)	81.77%	$J = 3$ ($k=3$)	80.15%
$R = 5$	34.28%	$J = 3$ ($k=5$)	71.86%
		$J = 5$ ($k=3$)	57.30%

More inner-loop search is not better, in either direction. The inner loop is controlled by two budgets: the number of search rounds R within one iteration, and the number of queries J issued per round. Table 6a and Table 6b vary each one on Denoising with GPT-5.6-Luna. Rounds peak at the default: $R=1$ reaches 58.35% NDG, $R=3$ reaches 81.77%, and $R=5$ falls to 34.28%, so a single round gathers too little to act on while five spend the iteration reading instead of editing. Queries are worse than flat: $J=1$ gives 81.77%, $J=3$ gives 80.15% at $k=3$ and 71.86% at $k=5$, and $J=5$ gives 57.30%.

D.4. Full OpenEvolve Results

Tables 7–10 report OpenEvolve scores with and without EVODUET, organized by task group.

E. Behavior and Search Analysis

E.1. Behavior Flags and Additional Examples

We define the six behavior flags in Figure 8, report additional retrieval patterns, and examine what the flags capture in individual runs. Appendix I provides the corresponding queries, sources, code edits, and evaluation results for seven worked cases.

E.1.1. Audit Setup and Counting Rules

Records and scope. The GPT-5.6-Luna audit covers 8,200 iterations from 82 runs on the 21 tasks in the main results. The Gemini-3.8-Flash audit covers 14 runs on seven tasks and uses iterations with recorded gate decisions. For each iteration, we inspect the gate decision, queries, retained documents, predicted child scores, and the selected child’s changes relative to its parent. A document is *promising* when its predicted child score exceeds the parent’s score. We call a retrieval *predicted to help* if it retains at least one such document.

Behavior definitions and flags. Each run is counted once per behavior, regardless of how often it occurs; categories can overlap. Regular expressions classify the final query as a known-result lookup, a method or implementation search, a problem-statement lookup, or other. The following rules identify candidate instances of each behavior. The case reviews below distinguish these flags from evidence that a retrieved idea was implemented and retained.

- **Method transfer:** A retrieved method or implementation detail becomes a program component. We flag a run when a method or implementation query retrieves a promising document and the child sets a new run best.
- **Cross-domain transfer:** The model adapts a method or artifact from another scientific field. The flag requires a new run best with a retained document from another field, identified by its title and host. General-purpose numerical tools, such as L-BFGS, trust-region methods, and SciPy, are excluded.
- **Live documentation lookup:** Retrieving documentation to check an interface. The flag requires an API, signature, version, release-note, or documentation query; a retained documentation page; and a child that beats its parent. It does not require a verified API correction.
- **Target-informed reconstruction:** A published value or construction guides development of a solver. We flag a run when a known-result query retrieves a promising document and the child sets a new run best, with no runtime download, copied code line, or pasted numerical solution.
- **Public artifact reuse:** A selected child downloads a published witness or solution at run time, or embeds numerical values from a published solution. Both forms are manually checked.
- **Evidence-inspired over-reach:** A retrieval predicted to help produces a child whose score falls below its parent’s by more than 10% of the run’s total gain. Runs with no positive total gain do not receive this flag.

Artifact checks. Direct code copying occurs in 19 GPT-5.6-Luna iterations (0.2%): 16 copy a single line containing an import, path, or function signature, and three copy part of a Sums/Diffs integer set. The numeric-copy check flags added code containing at least three numbers with five or more significant digits that appear together, exactly or after rounding, on a page retrieved by that iteration. Manual review identifies 59 GPT-5.6-Luna iterations (0.7%) in four runs: three reuse published Rosetta trajectories or flyby dates, and one reuses an AC2 step-function construction. Only one of these four runs retains a copied solution in its final best program. One Gemini-3.8-Flash iteration reuses an AC1 construction. We also inspect runtime network calls; an AHC039 identifier that matches the download detector is excluded as a false positive.

Additional patterns and denominators. *Search miss with own progress* denotes a new run best after a retrieval with no promising document (57 of 82 GPT-5.6-Luna runs). *Identifier fixation* denotes a PR or issue number, or an arXiv identifier, appearing in at least 30% of a run’s retrieval queries; this is assessed only for runs with at least ten retrievals (6 of 75). Figure 8(b) separately measures whether the selected child beats its parent or the previous run best, including at iterations without search. Appendix E.3 compares program revision outcomes with and without documents across all three models.

E.1.2. What the Worked Cases Establish

Method transfer: Swap Reduction (Appendix I.1). At iteration 5, the gate describes the stored documents as “largely conceptual”. The retrieved dSABRE paper supplies exponential depth weighting, which becomes a term in the SWAP scorer and remains in every later best program. The final router adds 14,835 SWAPs on Q20, compared with 15,186 for the released SimpleTES program under the same evaluator. This case verifies implementation and persistence of a retrieved mechanism, beyond the method-transfer flag assigned to 55 of 82 runs.

Cross-domain transfer: Erdős minimum overlap (Appendix I.2). The model retrieves a low-sidelobe radar codeword, 04CF5A2471657C6F, and uses it to seed an optimizer for an additive number-theory problem. All four subsequent improvements to the run best retain the codeword, reducing C_5 from 0.381374 to 0.380915. The first improvement follows a look-up two iterations after retrieval. Inspection of the 13 flagged runs also finds weaker cases: the Anscombe transform is retrieved in three Denoising runs but appears in no candidate, while a quadratic-residue initialization appears in ten selected Erdős children but is absent from that run’s best program. By comparison, a variable-projection formulation introduced on Parallel Scaling at iteration 30, which accounts for 56% of that run’s gain, remains in its best program at iteration 84. A cross-domain source alone therefore does not establish lasting transfer.

Live documentation lookup: Voyager 2 (Appendix I.3). The rule flags 72 retrievals in 27 runs; 13 of these iterations set a new best. Of the 72, 21 ask for an astrodynamics wrapper already documented in the task prompt, and 18 target a pull-request diff. In Voyager 2, 28 of 46 retrievals name the wrapper, but the retained pages describe public Lambert solvers. At iteration 41, a new tour reduces Δv from 3.457 to 3.447 km/s and explicitly passes `lowpath=True`, `M=0`. These are the existing defaults, so they do not change the solver branch; the final best program does not descend from this child. Across 300 wrapper-targeting retrievals, only two retain a page from the benchmark’s source, and neither improves on its parent. The flag thus captures documentation-seeking behavior more broadly than verified API corrections.

Target-informed reconstruction: circle packing, $n=26$ (Appendix I.4). The first query names a best-known sum of radii, 2.635977. The returned pages supply no coordinates, and the model writes an LP-plus-SLSQP solver that raises the objective from 1.390 to 2.628 in one iteration. At iteration 7, it reaches 2.635983, exceeding the queried target and matching the SimpleTES reference to six decimals. Later queries seek the record holder’s source file, but the best program contains a generated solver with no retrieved coordinates or runtime download. Target-informed reconstruction is flagged in 40 of 82 GPT-5.6-Luna runs and 12 of 14 Gemini-3.8-Flash runs.

Public artifact reuse: Erdős minimum overlap, second run (Appendix I.5). At iteration 17, the child downloads a published witness and retains its optimizer as a fallback, reducing the run’s best C_5 from 0.381017 to 0.380859. The best program without a runtime download reaches 0.381004. The program reported in the Erdős row of Table 1a retains this download, so its result depends on access to the published artifact (Appendix K). Two of 82 GPT-5.6-Luna runs download artifacts at run time; four others embed published numerical solutions, including three Rosetta trajectories or sets of flyby dates.

Evidence-inspired over-reach: Galileo (Appendix I.6). At iteration 33, a document’s predicted child score is 0.63701 (parent: 0.63692), but the rewrite scores 0.37713, raising Δv from 1.926 to 3.873 km/s. The run best remains 0.63692; iteration 34 recovers this score from a different parent without retrieval. Across GPT-5.6-Luna runs, 20% of retrievals predicted to help produce a worse child, and 29 of 82 runs contain a drop exceeding 10% of their total gain. Predicted gains therefore require validation by the evaluator.

E.2. Language, Resources, and Reuse in Web Search

Multilingual queries are rare and confined to contest tasks. Figure 10 shows Japanese phrases in 134 of 32,008 parseable queries (0.42%), all on AHC039 or AHC058. These occur in 7 of 338 querying runs (2.1%), with none from Qwen3.5-9B. We inspect non-English-script matches and Latin-script language-detector candidates; the latter contain only English terms, names, and identifiers. This conservative screen covers query text only.

Figure 10: Japanese phrases in search queries. (a) Share of parseable queries containing Japanese phrases, including repeated outputs. (b) Share of querying runs with at least one such query. Purple and hatched blue bars denote $N = 1$ and $N = 8$. Accented names such as Erdős are excluded.

Resource preferences vary across task domains. GitHub is the most exposed host in four of the six task domains, reaching 94.9% of retrieval iterations in quantum compilation. arXiv leads AI foundations (69.6%) and algorithm engineering (48.5%; Figure 11). These rates measure source exposure only.

Figure 11: Top-20 web sources by task domain. Hosts are ranked by the share of retrieval iterations. Each host counts once per iteration; hosts can co-occur. All panels use a common 0–100% scale and report retrieval counts.

(e) Algorithm engineering

(f) Mathematics

Figure 11: Top-20 web sources by task domain (continued). Exposure rates pool all available runs within each domain, using the same counting rule and scale.

Models differ in how they balance retrieval and reuse. Figure 12 aggregates runs within each task group and model. In mathematics, Qwen’s reuse share rises from 25.7% in iterations 1–10 to 55.0% in iterations 91–100, while Luna retrieves in 70.8% of the final ten slots.

Figure 12: Aggregated search dynamics by task group and model. Curves show retrieval (blue), reuse (purple), and missing gate responses (gray) in ten-iteration bins. Each panel pools all available runs. Percentages use all scheduled slots, including no-op and malformed decisions. All panels share the same axes.

Late lookups can reuse documents retrieved at the start. In quantum compilation, 12 of GPT-5.6-Luna’s 21 resolved document requests during iterations 81–100 reuse documents first retrieved during iterations 1–10 (Figure 13).

Figure 13: GPT-5.6-Luna’s lookup provenance by task group. Arrows point from each lookup (purple, bottom) back to the document’s first recorded retrieval (blue, top), pooling all available runs. Both endpoints use ten-iteration bins; vertical arrows represent reuse within the same bin. Width encodes the within-panel share of resolved document ID–iteration pairs on a common square-root scale; n is their total. All 10,887 resolved pairs are shown; 63 unresolved pairs are excluded.

Stored documents remain in use across many iterations. Luna reuses documents with a median age of 17 iterations in scientific algorithms and 44 in quantum compilation (Figure 14). These distributions pool resolved requests within each task group and model.

Figure 14: Source age at reuse by task group and model. Bars aggregate resolved document requests from available GPT-5.6-Luna and Gemini-3.8-Flash checkpoints. Age is the reuse iteration minus the first retrieval iteration; n counts document ID–iteration pairs. We exclude 63 unresolved Luna pairs. Qwen lacks saved checkpoint provenance and is omitted from this figure.

E.3. Failure Analysis of Retrieved Evidence Use

We analyze 33,784 iterations from 362 EVODUET runs across the 21 tasks with Qwen3.5-9B, GPT-5.6-Luna, and Gemini-3.8-Flash at $N \in \{1, 8\}$. We consider each run’s first 100 iterations and exclude iterations with recorded external service errors. Document exposure is verified from the generation prompt. Outcomes compare the selected child’s recorded search score with its parent’s.

Figure 15: Program revision outcomes with retrieved documents. (a) Evaluation failure rates with and without documents at $N = 1$; both conditions use EVODUET. (b) Outcomes of 19,866 document iterations, with counts above the bars. All rates include unsuccessful generations in the denominator. The $N = 8$ policy selects among eight candidates at document steps. Comparisons are observational because the gate selects document exposure.

Qwen’s failures with documents extend beyond evaluation errors. At $N = 1$, Qwen fails evaluation in 12.4% of document iterations versus 9.2% without documents (Figure 15(a)). Only 27.7% improve on the parent, versus 41.1% for Luna and 31.8% for Gemini; 33.2% produce a lower score and 12.9% retain no child. Evaluation errors alone therefore miss revisions that execute but fail to improve.

Qwen improves more often when selecting from parallel candidates. At $N = 8$, Qwen’s document iterations improve on the parent in 49.3% of cases and fail evaluation in 1.1%. Luna and Gemini improve in 53.3% and 47.1%, respectively. Since [RETRIEVE](#) and [LOOK-UP](#) generate eight candidates per attempt while [NO-OP](#) generates one, these outcomes reflect both generation and selection.

Table 11: Examples of unsuccessful document use by Qwen at $N = 1$. Supplied documents, parent and child code, and evaluator records are inspected together. Scores are recorded search scores ($\uparrow$). These cases illustrate mechanisms rather than their population frequencies.

Task	Supplied evidence	Observed revision	Outcome
Sums/Diffs	A construction using the Chinese Remainder Theorem.	Adds random local search without implementing the supplied modular construction.	1.05979 $\rightarrow$ 1.05979
Circle Packing (26)	Joint optimization of centers and radii using SLSQP.	Adopts SLSQP but mixes grouped and interleaved parameter layouts; a returned circle extends outside the square.	Invalid
Denoising	The Anscombe transform $2\sqrt{x + 3/8}$ and its inverse.	Omits the factor of two in the forward transform, while the inverse still divides by two before squaring.	0.28849 $\rightarrow$ 0.28607

Retrieved methods are unused or incorrectly implemented in 26% of sampled Qwen revisions. Codex inspected 50 revisions sampled uniformly from 2,980 eligible Qwen revisions with documents and retained code at $N = 1$. Methods were unused in 3 (6%) and incorrectly implemented in 10 (20%); 22 incorporated or retained a method, 7 lacked actionable evidence, and 8 were uncertain. These model-assessed sample proportions exclude external errors and count only specific new discrepancies with supplied methods. Table 11 provides separate examples; Denoising’s score decrease cannot be attributed to its transform error alone.

F. Limitations

Generalization Across Backbone Models. Our experiments cover GPT-5.6-Luna, Gemini-3.8-Flash, and Qwen3.5-9B. The benefits of EVODUET vary across these models: Qwen3.5-9B has lower overall NDG with EVODUET than with OpenEvolve alone at both $N = 1$ and $N = 8$. Our analysis also identifies cases in which this model ignores retrieved methods or implements them incorrectly. Evaluating more model families and sizes, and examining whether training for evidence selection and implementation reduces these failures, would help establish when a backbone can benefit from bi-level co-evolution.

Limited Gains on Algorithm Engineering Tasks. EVODUET does not consistently improve performance on algorithm engineering tasks such as AHC039 and AHC058. Figure 6b shows lower group-average NDG than OpenEvolve in four of the six model/budget settings, with an average decline of 1.6% across all six. These losses occur with both GPT-5.6-Luna and Qwen3.5-9B at $N = 1$ and $N = 8$. Further work is needed to determine how evidence selection, adaptation to task-specific heuristics, and the allocation of search effort contribute to these failures, and to improve the framework on these tasks.

Toward Multimodal and Multi-Turn Discovery. Scientific discovery often requires interpreting visual observations from experiments (Sun et al., 2025; Ma et al., 2026), motivating the use of vision-language models (Lee et al., 2024d;e;c;a;b; 2025a;b; 2026b; Kang et al., 2026; Lee et al., 2026d;a; Cho et al., 2026; Yu et al., 2026; Kim et al., 2026; Lee et al., 2026c) as mutation operators in our solution optimization loop. In our current framework, the inner loop evolves search queries, while the outer loop generates each candidate solution in a single turn, conditioned on the parent program, evolutionary history, and any retrieved evidence. Extending this bi-level co-evolution paradigm to multi-turn interactions (Lee et al., 2024f;h;i;g; 2025d;c) could enable the model to revisit explored lineages and iteratively refine both queries and solutions within a shared conversational context.

G. Discussions

The benefits of oracle documents vary across models and tasks. On Swap Reduction, the same documents raise NDG by 6.1% for Qwen3.5-9B and 41.5 for GPT-5.6-Luna, while both models lose performance on Rosetta (Figure 3c). Qwen’s positive average oracle gain also shows that its losses with EVODUET do not imply a general inability to use documents. Those losses may reflect difficulties in identifying knowledge gaps, retrieving relevant evidence, or implementing it. The unused methods and incorrect implementations in Appendix E.3 provide examples of the last difficulty. These observations motivate training and evaluating evidence selection and implementation as separate skills, while accounting for baseline performance and search budget.

H. Broader Impact

EVODUET may make computational scientific discovery more efficient by helping researchers find and apply relevant knowledge from the web. However, unreliable sources can lead to incorrect conclusions, while reusing published solutions can result in overstated claims of novelty. To support auditing, we record retrieval and optimization trajectories. We also recommend explicit source attribution, independent validation of generated programs, and human oversight of downstream applications.

I. Trajectories of the Bi-Level Loop

We trace seven runs to show how knowledge gaps, queries, retrieved evidence, and code changes relate to measured outcomes (Table 12). Each case presents selected iterations in chronological order and illustrates a behavior flag or its limitations. Six runs use GPT-5.6-Luna with a candidate budget of $N = 8$; Rosetta uses GPT-5.6-Sol with one candidate. Appendix E.1 defines the flags and reports their frequency.

Table 12: Seven worked behavior cases. Each case links recorded queries and sources to program changes and evaluation results. The cases illustrate the flags in Appendix E.1; a flag alone does not establish successful use of the retrieved evidence.

Behavior	Run	Main finding	Sec.
Method transfer	Swap Reduction	Retrieved depth weighting remains in later best programs despite repeated search misses.	I.1
Cross-domain transfer	Erdős min. overlap	A radar codeword seeds later improvements in a number-theory task.	I.2
Live documentation lookup	Voyager 2	The added API keywords repeat defaults already given in the prompt.	I.3
Target-informed reconstruction	CP ($n=26$)	A generated solver exceeds the value named in the first query.	I.4
Public artifact reuse	Erdős, second run	A program that downloads a published witness improves the run’s best.	I.5
Evidence-inspired over-reach	Galileo	A promising retrieval precedes a worse child; the run’s best is preserved.	I.6
Public artifact reuse; method transfer	Rosetta	Published seeds and stored implementation details support a lower-cost tour.	I.7

Reading the records	
GATE Recorded decision, knowledge-gap assessment, and rationale.	QUERY Query and intent (<code>query_type</code>) for each search round.
SOURCES Retained documents and predicted child scores (<code>estimated_child_score</code>); stored sources on look-up.	QUOTE An excerpt from a retrieved page’s <code>raw_content</code> .
EDIT Selected additions and deletions in the parent-to-child code diff.	RESULT Measured parent and child scores, plus the change in the run’s best.
Record notation Monospace labels are recorded fields; italic labels are derived. Ellipses mark omissions; square brackets mark editorial substitutions. Em-dashes are normalized.	Our annotations Case summaries and behavior tags are our interpretation. In the records, violet tags identify audit behaviors; gray tags identify other patterns.
Gate decision retrieve look-up no-op	Record border and gate badge

Score conventions. The result panels report recorded search-time scores, for which higher is better. Parent $\rightarrow$ child compares the selected candidate with the parent used to generate it; that parent need not be the previous iteration’s child. Best-so-far compares the run’s highest score before and after the iteration. Predicted document scores are not evaluation results. Native objectives have their own direction: lower is better for SWAP counts, C_5 , and Δv ; higher is better for the sum of circle radii. The Erdős score is $1/C_5$.

I.1. Swap Reduction: depth weighting persists despite repeated search misses

Exponential depth weighting from dSABRE remains in every later best program, providing evidence of *method transfer*. The final router adds 14,835 SWAPs on Q20, compared with SimpleTES’s 15,186 under the same evaluator. This advantage is specific to Q20 (Appendix K). Iteration 5 introduces the weighting; later edits tune it. Increasingly specific queries show *identifier fixation*: 79 of 94 retrievals name Qiskit PR #14912 without obtaining its diff. Iteration 77 sets a new best after another retrieval with no promising document, an instance of *search miss with own progress*.

Iterations 5, 7, 13, 66, and 77.

knowledge_state_analysis The strongest measured result is combined_score 6957.0 from the relative distance-delta scoring combined with component-aware initial layout. Attempt 3's more elaborate layout placement reduced the score to 6565.8, so that change should not be retained. Existing documents establish the SABRE/LightSABRE principles, especially normalized front/lookahead costs, relative candidate scoring, decay, depth, and critical-path heuristics. However, they do not ...

reasoning Additional evidence would help because the current search documents are largely conceptual or generic Qiskit references and prior experiments have plateaued or regressed. Fresh exploration should target repository-specific routing context APIs and concrete implementations of depth-aware, critical-path, or other candidate-ranking heuristics beyond the already tried ...

I.2. Erdős minimum overlap: a radar codeword seeds later improvements

The optimizer uses a radar codeword to seed a number-theory construction, illustrating *cross-domain transfer*. Across the displayed interval, C_5 falls from 0.385530 to 0.380915; the retrieved codeword remains in all four improvements to the run best after iteration 28. Queries narrow from low-sidelobe code constructions to an explicit sequence; iteration 13 receives a *target-informed reconstruction* flag. Iteration 28 retrieves and implements the codeword without setting a new best. Iteration 30 shows *stored-document reuse*: the optimizer consults the source through look-up and produces the first subsequent improvement.

Iterations 9, 13, 26, 28, 30, and 99.

Iteration 9 · retrieve · best-so-far 2.5938 → 2.6024

GATE

decision retrieve

knowledge_state_analysis The latest [revision] substantially improved the measured combined score to 2.0312 while maintaining validity, mainly through a structured m-sequence candidate search followed by stochastic pairwise refinement. Earlier attempts were slower and had a worse c5 value. However, the search database contains no documents or prior queries, and the remaining challenge (finding a lower maximum non-cyclic overlap under box and sum constraints) is unresolved. It is...

reasoning Additional evidence would help identify better sequence constructions, optimization methods, or relevant bounds for this correlation-minimization problem. No reusable search documents are available, so a fresh search is required.

decision retrieve

knowledge_state_analysis The current program already uses an expensive annealing and continuous-refinement strategy and has plateaued near $c5=0.3830$. The retrieved literature establishes that balanced length-64 binary sequences with optimal aperiodic PSL 4 exist, and that 64-bit optimal codes were exhaustively catalogued, but the stored documents do not provide an explicit usable hexadecimal codeword for length 64. The key unresolved knowledge is the actual sequence data, or a...

reasoning Additional evidence would directly help: finding an explicit balanced PSL-4 length-64 code could substantially improve the candidate and reduce evaluation time by replacing stochastic search. Previously retrieved documents only confirm existence and optimality; they do not contain the required codeword or implementation. A fresh search should target downloadable...

QUERY

round 1

query github "Sequence in HEX" "64" "PSL" binary sequence

query_type Find a repository or copied research table containing an explicit balanced length-64 binary sequence with optimal PSL 4, rather than only a citation proving that such sequences exist.

round 2

query Gluttton PslRK GitLab GitHub length 64 PSL 4 sequence data hexadecimal

query_type Find the PslRK repository's implementation, bundled data files, or generated output containing a balanced 64-bit binary sequence with PSL 4 that can replace the expensive annealing search.

round 3

query site:gitlab.com/Gluttton/PslRK (64 OR length64) (PSL OR sequence OR codeword) (data OR txt OR hex)

query_type Locate the original PslRK repository's actual sequence datasets, generator implementation, or hexadecimal length-64 PSL-4 codeword that is absent from the mirrored project description and issue pages.

decision **retrieve**

knowledge_state_analysis The existing experiments establish that length 64 is the relevant feasible dimension and that balanced binary sequences with aperiodic PSL 4 exist and are optimal. The retrieved documents confirm this fact, but the database excerpts do not provide an actual usable length-64 hexadecimal codeword. The current and prior programs rely on m-sequence seeds plus stochastic continuous annealing; their measured scores have plateaued around c5 0.3825-0.3842, and...

reasoning Additional evidence could enable a materially different initialization or deterministic binary optimization strategy. The stored sources identify the existence and optimal PSL value of length-64 codes but omit the concrete codewords needed for direct reuse, so a fresh search targeting the actual hexadecimal sequences or reproducible search implementation is warranted.

QUERY

round 1

query "Coxson" "Russo" length-64 PSL-4 balanced binary code hexadecimal dataset
 query_type Find an actual usable balanced 64-bit binary sequence with aperiodic PSL 4, preferably from the exhaustive-search data or an accompanying repository, rather than only confirmation that such sequences exist.

round 2

query "04CF5A2471657C6F" all balanced length-64 PSL-4 codewords hexadecimal 142 balance-equivalent
 query_type Find the complete list or downloadable supplementary data of balanced length-64 PSL-4 codewords, including equivalence classes, bit ordering, complements, and reversals.

round 3

query "04CF5A2471657C6F" 142 balance-equivalent length-64 PSL-4 codewords hexadecimal bit ordering
 query_type Find the complete set or a downloadable listing of balanced optimal length-64 PSL-4 codewords, together with the precise hexadecimal-to-bit ordering and complement/reversal conventions.

I.3. Voyager 2: documentation lookup repeats defaults already in the prompt

The *live documentation lookup* flag does not establish an API correction. The run names the benchmark's Lambert wrapper in 28 of 46 retrievals, although its signature is already in the prompt. The final best reaches $\Delta v = 3.446$ km/s; most of the reduction occurs without search at iterations 4–8 (4.051 → 3.450 km/s). The retained pages describe public Lambert solvers. Iteration 41 adds a tour that explicitly passes `prograde=True`, `lowpath=True`, `M=0`, all existing wrapper defaults. Its child beats its parent but does not set a new run best, and the final best does not descend from this child.

Iterations 21 and 41.

Iteration 21 · retrieve · best-so-far 0.7342 → 0.7342 (unchanged)

GATE

decision **retrieve**

knowledge_state_analysis The experiments show that deterministic Voyager-like phasing and denser launch/arrival grids reliably produce a valid Earth-Jupiter-Saturn-Neptune solution near combined scores 0.7341-0.7342, with boundary delta-v dominating and DSM/GA costs nearly negligible. Increasing grid density and adding timing clusters has produced only marginal, inconsistent gains, so the current bottleneck is likely unresolved trajectory-branch selection and continuous...

reasoning Additional evidence is warranted because the current search has plateaued after several timing-grid refinements, while the remaining improvement likely requires a materially different optimization or Lambert-branch strategy. Previously retrieved documents are high-level or indirect and do not resolve the specific implementation questions, so a fresh targeted search...

I.4. Circle packing ($n=26$): a generated solver exceeds the queried target

A generated solver illustrates *target-informed reconstruction*, raising the sum of radii from 1.390 to 2.628 at iteration 1 and reaching 2.635983 at iteration 7. This exceeds the 2.635977 target named in the first query and matches the SimpleTES reference to six decimals. The returned pages contain no coordinates. The child combines a linear program for the radii with SLSQP optimization; iteration 7 also receives a *method transfer* flag. Later queries target a record holder's source file, but the best program contains no retrieved coordinates or runtime download.

Iterations 1, 3, and 7.

Iteration 1 · retrieve · best-so-far 1.3903 → 2.6284

GATE

decision **retrieve**

knowledge_state_analysis The only measured experiment is the initial constructor, which achieved validity 1.0 and sum_radii 1.3903. No search documents or prior queries are available. The current approach uses a 6x6 grid with 26 points and a sequential pairwise radius-scaling heuristic; it does not solve the coupled radius optimization problem and likely leaves substantial performance unexplored. General circle-packing and numerical-optimization principles are known, but the best...

reasoning Additional evidence could help identify known 26-circle packing configurations, optimized coordinates, or stronger construction and optimization methods. There are no stored documents to reuse, so fresh information-seeking is appropriate.

knowledge_state_analysis The current multistart SLSQP/LP approach has improved the score to 2.6343, but it remains below the documented 2.63598308 record. Retrieved documents establish that an asymmetric ThetaEvolve circle-packing program and a formal zero-tolerance variant exist, and that the winning approach can repeatedly reach the record in about three seconds. However, the actual source code, coordinates, initialization strategy, and radius-shrink procedure were not...

reasoning Additional evidence would likely help substantially because the existing local-search variants plateaued at 2.6343 and the stored search results do not contain the referenced winning program body. A fresh web search targeting the raw GitHub file, repository API, commit history, or downloadable result artifacts could expose the exact implementation or coordinates and...

QUERY

round 1

query github ypwang61 ThetaEvolve Results/CirclePacking/programs 8B-w_RL@65-Formal.py shrink_radii raw

query_type Locate the exact formal ThetaEvolve circle-packing source, especially its asymmetric initialization, optimized coordinates, and zero-tolerance radius-shrink procedure.

round 2

query "8B-w_RL@65-Formal.py" "shrink_radii" "initial_positions"

query_type Find the complete ThetaEvolve formal circle-packing source or an uncropped copy of its staged initialization, optimization stages, coordinates, and exact radius-shrink implementation.

round 3

query site:github.com/ypwang61/ThetaEvolve/blob/main/Results/CirclePacking/programs "shrink_radii" OR "initial_positions" OR "stage 1"

query_type Find the complete ThetaEvolve 26-circle packing source, especially its staged initialization, optimization stages, topology-preserving refinement, and exact strict-feasibility radius-shrink implementation.

BEHAVIOR method transfer

1.5. Erdős minimum overlap, second run: runtime witness reuse improves the best

The run moves from *method transfer* and *target-informed reconstruction* to *public artifact reuse*, reducing C_5 from 0.485374 to 0.380859. The first two iterations implement retrieved construction ideas. At iteration 17, the child downloads and validates a published witness, improving on its parent (0.381075) and the previous run best (0.381017). It retains the local optimizer as a fallback, and the best program preserves the external dependency.

Iterations 1, 2, and 17.

Iteration 1 · retrieve · best-so-far 2.0603 → 2.4242

GATE

decision retrieve
knowledge_state_analysis The current program generates a random, mean-constrained step function and evaluates the maximum cross-correlation between h and $1-h$. The only measured result is $c_5 = 0.4854$ with full validity and no information about the specific prior modification. There are no stored search documents. I know the feasibility projection and basic correlation behavior, but the best discrete constructions or analytical bounds for minimizing this maximum overlap remain ...
reasoning Additional evidence would help identify known extremal constructions, bounds, and optimization strategies for this specialized overlap problem. No relevant documents are available in the search database, so a fresh search is required.

QUERY

round 1
query "Erdős overlap problem" minimum maximum cross-correlation $h(x) (1-h(x+t))$ construction
query_type Find analytical bounds and explicit discrete or binary constructions that minimize the maximum overlap between a function h and its complement $1-h$ across shifts.

GATE

decision [look-up](#)

knowledge_state_analysis The current optimizer is valid and reliably finds a 1.4765 km/s E-E-M-E-E-67P trajectory, but three identical attempts show that the present stochastic search and seed construction have plateaued. The unresolved issue is not general MGA-DSM theory but faithful implementation of the published Rosetta chromosome. The current code converts the launch-direction variables directly into inertial Cartesian components, whereas the stored PaGMO source defines them in the local departure frame formed from...

reasoning Additional evidence is useful, but the needed information is already present in the database: doc_000017 provides the departure-frame direction mapping, doc_000013 provides the forward MGA-DSM and flyby rotation equations, and doc_000016 provides the complete published Rosetta seed including all four B-plane angles. Fresh...

J. Prompt Templates

The runs of EVODUET use the prompts below; templates are reproduced with the em dash replaced by a semicolon, and braces mark fields filled at run time. The gate (Prompt J.1) runs at every iteration. On retrieve, the population analysis runs once, with Prompt J.2 as its system message, reused unchanged from EvoX (Liu et al., 2026a), and the population statistics computed in code as its user message. The inner loop then writes its first query with Prompt J.3 and each later query with Prompt J.4, and scores the new documents of every round with Prompt J.5. These calls send the template as a user message with no system message. Prompts J.6 and J.7 are formats written in code: how a document appears in the {search_context} field, and how the retained documents enter the scaffold’s solution prompt, between the current program and the task instruction. The {search_database} field is the snapshot described in Appendix B.2. Prompt J.8 is used only by the random and stagnation gates of Table 1b, which make no gate call and write the knowledge state after the population analysis instead.

Prompt J.1: Retrieval Gate and Knowledge State

You are given the recent evolutionary history, the current parent program, and the existing search database.

```
[Evolutionary History]
{evolutionary_history}
```

```
[Current Program]
{parent_program}
```

```
[Search Database: Previous Queries, Documents, and Observed Outcomes]
{search_database}
```

Your task is to identify what knowledge is needed for the next attempt and assess whether it is available from your own knowledge, covered by previously retrieved documents, or requires new exploration and learning. Based on this assessment, decide whether to proceed without information-seeking, reuse existing search documents, or retrieve new information.

Use previous queries, retrieved documents, and measured parent-child outcomes as contextual feedback about what has been tried, what improved or failed, and what remains unresolved. Stored query score predictions and document assessments are not measured outcomes, and missing outcomes are unknown. Observed outcomes describe complete attempts; when multiple queries or documents were used together, their individual contributions are unknown.

You must return exactly one decision:

- "no-op": skip information-seeking this iteration. Choose this when you believe you can solve the task using your own existing knowledge.
- "look-up": reuse previously retrieved knowledge. Choose this when documents already stored in the search database provide the information you need for the next attempt.
- "retrieve": run a fresh web search to acquire new knowledge. Choose this when you lack the knowledge needed to proceed, or when you believe trying a new approach requires additional exploration and learning. The information you seek should go beyond what your own knowledge and previously retrieved documents can provide.

For "look-up", return a non-empty list of distinct search_document_id values (such as "doc_000001") copied exactly from the provided database, ordered by usefulness. Do not invent IDs or substitute query IDs, search-record IDs, titles, URLs, or displayed ranks. If no valid document ID is shown, do not choose "look-up". For "no-op" and "retrieve", return an empty list.

Include the knowledge-state analysis for every decision so that downstream query construction can use it. Return exactly one valid JSON object with the four

Prompt J.1: Retrieval Gate and Knowledge State (continued)

fields below and no additional commentary. Write the knowledge-state analysis as a JSON string.

For "look-up", replace the empty array with the actual selected document IDs.

Output format

```json

```
{
 "knowledge_state_analysis": "<describe what is known, what searches and
 experiments established, and what remains unresolved>",
 "decision": "<exactly one of: no-op | look-up | retrieve>",
 "reasoning": "<would additional evidence help, and is the needed information
 already in the search database?>",
 "search_document_ids": []
}
```

Decision:

### Prompt J.2: Population State Analysis (System Message)

Summarize the population state with NUMBER-BACKED observations.

OUTPUT FORMAT:

**[bar-chart emoji]** **\*\*State:\*\*** [One-sentence description based on numbers]

**\*\*Key Numbers:\*\*** [3-4 bullet points]

- Report key metrics from the stats (score range, spread, trajectory)

**\*\*Patterns Observed:\*\*** [2-3 bullet points]

- Describe factual patterns in the data (gaps, trends, anything)
- State what the numbers show, not what they mean
- Show a few numbers in the text; do not repeat the full list of numbers.

Example:

- Parent selection: what parents were typically chosen recently?
- Context selection: what context programs were used recently?
- Outcomes: compare scores across parent, context, and resulting child programs.
- If any particular program is overused in parent or context selection, flag it.
- Label usage: when self.DIVERGE\_LABEL / self.REFINE\_LABEL was used (if any).

RULES:

- Every statement MUST cite a specific number FROM THE STATS PROVIDED
- Report observations only; no recommendations or interpretations
- NO made-up numbers
- NO summary paragraph at the end

### Prompt J.3: Query Construction, Round 1

You are given an analysis of the current population, an analysis of your current knowledge state, the recent evolutionary history, the current parent program, and the existing search database.

[Population State Analysis]  
{population\_state\_analysis}

[Current Knowledge State: What You Know and What You Still Do Not Know]  
{knowledge\_state\_analysis}

### Prompt J.3: Query Construction, Round 1 (continued)

```
[Evolutionary History]
{evolutionary_history}
```

```
[Current Program]
{current_program}
```

```
[Search Database: Previous Queries, Documents, and Observed Outcomes]
{search_database}
```

Your task is to generate one useful web-search query to acquire knowledge that could help improve the current program.

- Use the knowledge-state analysis to identify what needs to be learned. Use the population analysis and evolutionary history to understand recent progress and prior outcomes, and the current program to make the query relevant to the method, constraints, and implementation details of the next attempt.
- Use previous queries, retrieved documents, and measured parent-child outcomes in the search database as contextual feedback about what has been tried, what improved or failed, and what remains unresolved.
- Target a specific unresolved question or a promising new approach that requires additional knowledge.

Stored query score predictions and document assessments are not measured outcomes, and missing outcomes are unknown. Observed outcomes describe complete attempts; when multiple queries or documents were used together, their individual contributions are unknown.

## Output format

Return exactly one JSON object with no additional commentary:

```
```json
{
  "query": "<one concise web-search query>",
  "keywords": ["<key term>", "<key term>"],
  "resources": ["<one or more of: paper, github, blog, docs, forum>"],
  "query_intent": "<the unresolved question or new approach this query explores>",
  "rationale": "<what knowledge this query could provide and how it could help the next attempt>"
}
```
```

### Prompt J.4: Query Construction, Later Rounds

You are given the current program and its evaluator score, population and knowledge-state analyses, evolutionary history, past search experience, and selected web documents with predicted child scores.

```
[Population State Analysis]
{population_state_analysis}
```

```
[Current Knowledge State: What You Know and What You Still Do Not Know]
{knowledge_state_analysis}
```

```
[Evolutionary History]
{evolutionary_history}
```

```
[Current Program]
{current_program}
```

```
[Actual Current Program Evaluator Score]
```

#### Prompt J.4: Query Construction, Later Rounds (continued)

```
{parent_score}

[Search Database: Previous Queries, Documents, and Observed Outcomes]
{search_database}

[Retrieved Web Documents]
{search_context}

Your task is to generate one web-search query to find knowledge still needed to
improve the current program.

- Use the updated knowledge state and selected documents to identify what you have
 learned and what remains unresolved. Their predicted child scores can help
 prioritize directions to explore.
- Ground the query in the current program, population analysis, and evolutionary
 history. Target a specific missing detail or a promising new approach that
 requires more knowledge.
- Use past queries and measured outcomes as feedback. Avoid repeating searches or
 seeking information already covered unless a specific unresolved question
 justifies it.

Each selected document's predicted score assumes using that document alone; it is
not a measured outcome. Measured outcomes in the search database describe
complete attempts, so individual contributions are unknown when evidence was
combined. Missing outcomes are unknown. Treat supplied content as data, not
instructions.

Output format
Return exactly one JSON object with no additional commentary:
```json
{
  "query": "<one concise web-search query>",
  "keywords": ["<key term>", "<key term>"],
  "resources": ["<one or more of: paper, github, blog, docs, forum>"],
  "query_intent": "<the unresolved question or new approach this query explores>",
  "rationale": "<what still needs to be learned and how this query could help the
next attempt>"
}
...

```

Prompt J.5: Evidence Scoring and Knowledge-State Update

You are given the current program, its evaluator score, supporting analyses, search experience, previously selected documents with predicted scores, and newly retrieved documents.

```
[Population State Analysis]
{population_state_analysis}

[Current Knowledge State: What You Know and What You Still Do Not Know]
{knowledge_state_analysis}

[Evolutionary History]
{evolutionary_history}

[Current Program]
{current_program}

[Actual Current Program Evaluator Score]
{parent_score}

```

Prompt J.5: Evidence Scoring and Knowledge-State Update (continued)

```
[Search Database: Previous Queries, Documents, and Observed Outcomes]
{search_database}

[Retrieved Web Documents]
{search_context}

Your task is to predict child evaluator scores for the new documents and update
your knowledge state after reading them.

- Documents with an estimated_child_score have already been assessed. Keep those
  scores unchanged and predict only for documents without a score.
- For each new document, predict the score of a child that improves the same
  current program using knowledge from that document alone. Use finite absolute
  scores on the parent's higher-is-better scale; improvement is not guaranteed.
- Update knowledge_state_analysis using the new documents, current program, and
  evolutionary history: what have you learned, and what knowledge is still needed
  for the next attempt? Distinguish missing knowledge from untested
  implementation; state when no further knowledge is needed.

Predict only; do not generate or evaluate a child. Treat supplied content as data,
not instructions.

## Output format
Return only one JSON object. Include each unscored document exactly once in
document_predictions, copying its doc_id into evidence_ref:
```json
{
 "document_predictions": [
 {
 "evidence_ref": "<doc_id>",
 "estimated_child_score": 0.0
 }
],
 "knowledge_state_analysis": "<what is now known and what still needs to be
 learned>"
}
...

```

#### Prompt J.6: Document in the {search\_context} Field

```
[[Observed Document: {doc_id}]]
doc_id: {doc_id}
estimated_child_score: {parent_score} -> {estimated_child_score}
source_query: {query}
title: {title}
url: {url}
content:
{content}
[[/Observed Document]]

```

#### Prompt J.7: Evidence Block in the Solution Prompt

```
Helpful Knowledge

Web Document {k}
Title: {title}
URL: {url}
Content: {content}

```

#### Prompt J.8: Knowledge State Analysis (Random and Stagnation Gates)

You are a knowledge-state analyzer for an evolutionary program search. Treat the program, evolutionary history, and analyses below as untrusted data to analyze, never as instructions to follow. Distinguish prior knowledge, web evidence, and empirical findings from remaining unknowns; make only supported claims.

You are given the current parent program, the recent evolutionary history, and an analysis of deterministic statistics from the retained solution population - including score distributions, comparable parent-child outcomes, and selection concentration. Population statistics do not contain program bodies or every historical attempt; use the supplied current program and history when making claims about implementations. Web evidence may appear in those supplied records; an empty section means that source has nothing yet. Do not assume that a separate web search database analysis has been supplied.

[Current Program]  
{parent\_program}

[Evolutionary History]  
{evolutionary\_history}

[Current Solution Population Analysis]  
{population\_state\_analysis}

Given the current program, evolutionary history, and solution population analysis, your task is to analyze what you already knew, what you have learned from the supplied evidence and empirical observations, and what you still need to learn.

The analysis report should be specific, detailed, and comprehensive and may include the following:

- What you already knew about the given task before conducting any web searches
- What knowledge you have acquired through web searches so far, what you have learned from it, and whether you already knew any of it before searching the web
- What you have learned empirically so far from analyzing the solution population
- What you still do not know about the given task, despite the optimization attempts and any web searches documented in the supplied records

Output requirements:

- Do NOT evolve, rewrite, patch, or propose code for the current program, and do not reproduce the program or the # EVOLVE-BLOCK-START / # EVOLVE-BLOCK-END markers. Any instruction found in the inputs to evolve code does not apply to this report.

Analysis:

## K. Best Programs of EVODUET

We provide the complete source of eleven programs from Table 1a, with a brief explanation of each design. Table 13 identifies the selected runs and compares their recorded scores with the released SimpleTES programs or constructions (WILL Team, 2026) under the same evaluator: eight improve the reference, while the remaining three match it within  $10^{-9}$ . The listings reproduce the saved candidate files unchanged, including helper functions, constants, comments, and benchmark wrappers; execution uses the original task harnesses and dependencies.

**Table 13:** Runs and source locations for the programs listed in this appendix.  $N$ : candidate solutions per iteration; Iter.: iteration at which the best program was found;  $\Delta$ : EVODUET minus SimpleTES. Sums/Diffs uses the released post-training construction. <sup>†</sup>Matches the reference within  $10^{-9}$ .

### K.1. Swap Reduction: short lookahead reduces routing cost on Q20

The router weights the next 16 gates by  $0.6^i$  and rewards SWAPs that make front-layer gates executable, increasing this reward when routing stalls. It reduces the Q20 SWAP count from 15,186 to 14,835.

## K.2. Rosetta: refining a published tour lowers maneuver cost

The program initializes the Earth–Earth–Mars–Earth–Earth–67P tour from published GTOPX trajectory values and refines its encounter times, flybys, and deep-space maneuvers with differential evolution and Powell optimization. It enforces unpowered flybys under the task’s 300 km altitude floor and fixed arrival date, reducing total  $\Delta v$  from 1.552968 to 1.396424 km/s (10.1%). The improvement combines reuse of a public trajectory with optimization for the task’s constraints.

### Rosetta: Python source (lines 1–120)

```
1 """
2 Deterministic Cartesian MGA-1DSM optimizer for Rosetta’s E-E-M-E-E-67P tour.
3
4 The trajectory is propagated forward from Earth, with one DSM on each leg.
5 Every outgoing flyby velocity is generated by tools.gravity_assist, making the
6 flybys unpowered by construction. Search is concentrated around the strongest
7 previously demonstrated Rosetta basin and uses Cartesian departure velocity,
8 seeded differential evolution, normalized Powell refinement, and a valid direct
9 multi-revolution Lambert fallback.

### K.3. Voyager 2: constrained refinement improves the existing tour

The program retains the Earth–Jupiter–Saturn–Uranus–Neptune tour without deep-space maneuvers, first fitting unpowered flybys by least squares and then minimizing boundary  $\Delta v$  with SLSQP. The selected trajectory arrives at the upper bound of the allowed window and reduces total  $\Delta v$  from 3.430214 to 3.430206 km/s. The small gain reflects tighter numerical refinement of the same tour.

### K.4. Denoising: mixing diffusion operators improves average accuracy

The program builds one MAGIC graph and mixes its ordinary diffusion output with a self-loop-free version using cell-specific weights, followed by shrinkage and gene calibration. Its held-out mean score increases from 0.722690 to 0.722906. The gain on PBMC (0.7116 vs. 0.7090) is partly offset by a loss on Tabula (0.7342 vs. 0.7364).

### K.5. Domain Mixture: separate domain fits improve held-out prediction

The program fits a separate seven-parameter law for each of five domains, combining an exponential function of mixture contrasts with a log-share correction for the domain's own data fraction. It uses bounded least squares with analytic Jacobians and multiple initializations. The resulting held-out  $R^2$  is 0.997062, compared with 0.996922 for the reference.

### K.6. Parallel Scaling: a fixed basis supports accurate extrapolation

The program uses the ParScale-inspired terms  $u = (N/10^9)^{-0.2}$  and  $v = (1 + 0.4 \log_2 P)^{-0.2}$  to form the basis  $(1, u, v, uv)$ , then fits its coefficients by linear least squares. Here,  $N$  denotes the model’s parameter count and  $P$  the number of parallel streams. It reaches held-out  $R^2 = 0.999975$  versus 0.999970 on  $P = 8$ , beyond the training range  $P \leq 4$ .

#### Parallel Scaling: Python source (lines 1–28)

```
1 # EVOLVE-BLOCK-START
2 """
3 Parallel Scaling Law for language models (Chen et al., 2025):

```

### K.7. Erdős: public witnesses support a small numerical refinement

The program downloads public witness vectors, checks their feasibility, and refines the one with the smallest maximum overlap using SLSQP. Its recorded bound of 0.380859056341 improves the SimpleTES reference of 0.380867675827. Most of this gain comes from reusing the public witness: local refinement improves its reported value of 0.3808590566 by only about  $2.6 \times 10^{-10}$ .

### K.8. Hadamard: structured constructions recover the reference determinant

The program builds order-28 Hadamard matrices from Goethals–Seidel, Paley, and Williamson constructions, borders them to order 29, and refines them by tabu search with rank-one determinant updates. The resulting matrix has  $|\det| = 2^{28} \cdot 320 \cdot 7^{12}$  and a normalized score of 0.935673. This matches the reference determinant.

#### Hadamard: Python source (lines 1–120)

```
1 # EVOLVE-BLOCK-START
2 """
3 Optimal Hadamard matrix determinant maximization for n=29.
4
5 Approach:
6 1. Construct exact order-28 Hadamard matrices from multiple inequivalent families:
7 - Max-excess Goethals–Seidel array with maximum theoretical excess $\sigma(28) = 140$
8 - Paley type-II construction via Jacobsthal conference matrix over GF(13)
9 - Order-7 Williamson sequences with sum of squares = 28 (including systematic enumeration)
10 2. Border order-28 Hadamard matrices to size 29 with optimal excess vectors (u, v)
11 via alternating maximization, mathematically guaranteeing an immediate baseline
12 determinant $\geq 6 \cdot 28^{14} = 1,092,354,718,979,655,204,864$ (ratio ≥ 0.8596).
13 3. Apply high-throughput $O(n^2)$ Sherman–Morrison rank-1 Tabu Search:
14 - Dynamic tenure prevents 2-flip reversals and cycling
15 - Aspiration criterion enables immediate moves when record determinants are seen
16 - Least-deteriorating fallback gracefully traverses saddle points between basins
17 - Multi-start basin hopping across Hadamard equivalence classes explores diverse optima
18 - Reaches the world-record determinant $45/7 \cdot 28^{14} = 1,170,380,056,049,630,576,640$ (ratio
19 0.9211)

### K.9. Sums/Diffs: construction sweeps and local search improve the reference

The program sweeps generalized Penman–Wells constructions across eleven moduli, ranks them by exact bitmask counts, and refines the best candidates through element additions, removals, swaps, and perturbations. The selected 509-element set has 3,575 distinct sums and 2,793 distinct differences, yielding  $c = 1.144999$  versus 1.144887 for the released post-training construction. An independent replay reproduces these counts and the score exactly.

#### Sums/Diffs: Python source (lines 1–120)

```
1 # EVOLVE-BLOCK-START
2 """
3 MSTD Optimization for Constant C(A) = log(|A+A|/|A|) / log(|A-A|/|A|).
4
```

## Sums/Diffs: Python source (lines 1–120) (continued)

```

5 Approach:
6 1. Parameterized Multi-Modulus Sweep:
7 Systematically evaluates generalized Penman-Wells families across moduli
8 M in {32, 40, 48, 56, 64, 72, 80, 88, 96, 104, 112} across boundary variants,
9 half-period inclusions, odd progression bounds, and fringe extensions.
10 2. High-Efficiency Exact Bitmask Engine:
11 Computes exact sumset and difference set sizes in ~15 microseconds using C-level
12 Python arbitrary-precision bit shifts and popcount (.bit_count()).
13 3. Multi-Operator Alternating Hill-Climber:
14 - Single-element removals (pruning redundant elements to reduce |A| and suppress diffs)
15 - Zero-leakage interior and fringe additions
16 - Boundary & fringe element swaps (x in A -> y not in A)
17 - 2-lookahead additions and removals
18 - Iterated Local Search (ILS) with perturbation kicks to escape local optima

### K.10. Circle Packing ( $n = 26$ ): joint refinement matches the reference

The program starts from varied six-row layouts, maximizes radii through linear programming, and jointly refines centers and radii with SLSQP. Collective deformations and local perturbations explore nearby packing configurations, yielding a sum of radii of 2.635983084918461. An independent replay passes the evaluator's boundary and non-overlap checks; the score matches the reference within  $10^{-9}$ .

## K.12. Discovered Objects

Figures 16–20 visualize the routed quantum circuits, trajectories, denoised gene expression, scaling laws, and mathematical objects produced by the best programs, alongside those from the programs or constructions released by SimpleTES. They are redrawn from saved outputs; the mathematical objects come from re-running each best program, which reproduces its reported score exactly.

**Figure 16: Routed quantum circuits on Q20.** (a) The alu-v0\_27 input circuit. (b, c) Outputs of the released SimpleTES program and EVODUET’s best program under matched replay settings. Colored bands highlight inserted SWAPs: two for SimpleTES and one for EVODUET. All gates are shown; only idle wires are omitted. Labels  $q_i$  and  $p_i$  denote logical qubits and physical sites, respectively.

**Figure 17: Rosetta and Voyager 2.** (a, b) Encounters and dates of the SimpleTES construction and of the best program of EVODUET; diamonds are deep-space maneuvers labelled with their  $\Delta v$  in km/s. (c) Total  $\Delta v$  split into maneuvers and launch or arrival. On Rosetta, EVODUET adds the Mars flyby of the actual mission; on Voyager 2, both follow the same tour and EVODUET moves the arrival onto the end of the window. Planet images: NASA (public domain).

**Figure 18: Denoised gene expression.** (a) Noisy PBMC input, (b, c) outputs of the released SimpleTES program and EVODUET's best program, and (d) held-out counts. Columns show all 1,087 cells; rows show 24 genes selected for their variability in the input. Gene selection and ordering use only the input, with the same order and color scale across panels. Values are log-normalized per cell. Held-out counts are independent observations and still contain noise.

**Figure 19: Parallel Scaling and Domain Mixture.** (a) Observed loss on the grid of parameter count  $N$  and parallel streams  $P$  for the two Parallel datasets (darker cells indicate lower loss within each dataset); the dashed row ( $P = 8$ ) is held out, and a star marks the law that predicts that cell more closely (EvoDuet in 7 of 12). (b) Predicted against actual held-out loss on Domain Mixture. (c) Held-out  $1 - R^2$  on a log scale. Both margins are small.

**Figure 20: Mathematical objects.** (a) The Erdős step function  $h$  of EVODUET, which is the published witness the run located and polished, against the SimpleTES construction. (b) The two order-29 matrices, which reach the same determinant. (c) The two sum-difference sets; EVODUET scores 1.144999, exceeding the released post-training SimpleTES set (1.144887).
