Abstract

We present YODAS v3, a weakly-labeled speech corpus containing over 1.1 million hours¹ of 48kHz multi-channel audio in 147 languages, released under a CC BY 3.0 license. YODAS v3 is not only the largest open speech dataset to date, but also the first truly large-scale speech corpus with high-fidelity stereo audio. We first provide the collection methodology for the corpus, where we introduce new techniques for gathering language-balanced speech data. The effectiveness of our approach is shown by the language distribution of the crawled data: 22 languages in YODAS v3 have over 10K hours and 73 languages have over 5K hours of data. We then conduct extensive analyses on the composition of the data, such as the distribution of languages, audio quality, and transcription quality. Finally, we train baseline speech recognition and neural codec models to show the effectiveness of the dataset. Download at <https://huggingface.co/datasets/espnet/yodas3>.

Index Terms: multilingual, data, stereo, large-scale

1. Introduction

The rapid advancement of speech foundation models [1–14] is primarily driven by the availability of massive and diverse audio corpora [15–19]. While proprietary systems benefit from internal datasets that can scale to over 10 million hours [20, 21] of audio, previous work [5] has shown that the combination of nearly all open speech corpora only sums to a little over 1 million hours of audio as of late 2024².

Furthermore, there is also a quality gap between open and propriety corpora. The vast majority of open-source speech datasets, such as YODAS v2 [17], VoxPopuli [15], MLS [23], and LibriLight [18] distribute data as monaural audio at sampling rates of 16 kHz or 24 kHz. While sufficient for standard ASR tasks, these constraints severely limit research in emerging domains that require high-resolution spatial audio, such as noisy multi-speaker ASR [24], high-fidelity audio codec modeling [25], full-band expressive TTS [26], spatial audio processing [27], and stereo speech enhancement [28]. Training models for these tasks requires high-resolution, multi-channel data, which has historically been scarce in open-access repositories.

Similar to how the release of corpora like VoxPopuli [15] and YODAS [17] helped enable new areas of research in open

large-scale self-supervised learning [5, 6, 29, 30] and large-scale supervised learning [2, 8, 31, 32], respectively, our goal is to empower future research that requires high-fidelity and/or spatial audio. We therefore introduce YODAS v3, a dataset containing more than one million hours of multilingual speech, making it the largest open speech dataset. Unlike prior large-scale collections, YODAS v3 preserves quality by saving it in the original downloaded format: 48kHz multi-channel OPUS files. Compared to other large-scale corpora, YODAS v3 is well-balanced across languages: 22 languages in YODAS v3 each have over 10K hours of data and 73 languages have over 5K hours. YODAS v3 also includes weak supervision in the form of automatically generated language identity tags, speech recognition transcripts, and English translations, making it also the first open supervised corpus at such scale. We first outline our data collection method for YODAS v3, in which we propose crawling techniques to better collect data for medium and low resource languages, and leads to a language-balanced corpora composition. We then perform analyses of the crawled data, including language distribution and audio characteristics. Finally, we train models using the crawled data to show the viability of our approach for Automatic Speech Recognition (ASR) and Neural Audio Codec modeling.

2. Data Collection

2.1. Keyword Generation

We first create lists of keywords for YouTube video search. In YODAS v2 [17], a shared keyword list across all languages is constructed from a multilingual Wikipedia dump data. This approach biases the keywords towards that of high-resource languages (such as English). This also results in reduced search quality, since words from the wrong language are used in the search term. Instead, we apply the following language-specific filters to create a keyword list for each language. For a given language, we download that language’s Wikipedia dump file and filter keywords that satisfy all of the following conditions:

- Not consisting of only punctuation and numbers.
- Neither punctuation nor a digit is the first character.
- 3–30 characters in length.
- Neither a filename, DOI (digital object identifier), a Wikipedia Template file, nor a Wikipedia Request file.

The final step is to filter out excessively rare words so that the keyword list is a manageable size for searching. We first train a unigram-based subword tokenizer [36] on the filtered keywords for each language. We predefine a unigram vocabulary size: if we cannot construct a vocabulary at that size, we halve the size and try again until we successfully build a vocab-

*These authors contributed equally.

¹After acceptance, we identified and removed duplicated videos, reducing the total from 1.4M to 1.1M hours. The distribution figures and counts reflect the corrected dataset; the paper’s findings are unchanged.

²While this number has now doubled to roughly 2 million hours after the release of [22], it is still a far cry from that of propriety corpora.

Table 1: A comparison of YODAS v3 with a other open large-scale speech datasets. YODAS v3 is the first public dataset to reach a scale of over 1M hours while supporting high-bandwidth stereo data.

Dataset	Languages	Size	Sampling Rate	Stereo	Labeled	License
Common Voice [33]	137	0.033M hours	48kHz	✗	✓	CC-0
MLS [23]	8	0.051M hours	16kHz	✗	✓	CC BY 4.0
FLEURS [34]	102	0.001M hours	16kHz	✗	✓	CC BY 2.5
VoxLingua107 [35]	107	0.007M hours	16kHz	✗	✓	CC BY 4.0
Librilight [18]	1	0.060M hours	16kHz	✗	✗	CC BY 4.0
VoxPopuli [15]	23	0.400M hours	16kHz	✗	✗	CC-0

YODAS v2 [17]	140	0.550M hours	24kHz	✗	✓	CC BY 3.0
YODAS v3 (this work)	147	1.100M hours	48kHz	✓	✓	CC BY 3.0

Figure 1: Histogram of video upload date. “YODAS2” is the submission deadline of ASRU 2023.

ulary. After training, we tokenize each keyword and compute its unigram likelihood. We finalized the keyword list for each language using only keywords with highest likelihood.

2.2. Video Search

We search for videos IDs using the generated keyword list. Similar to YODAS v2, we limit the search to only videos that are uploaded under a Creative Commons license. We also prioritize more recently uploaded videos, since YouTube’s default search engine settings favor videos that are highly relevant to the keywords and therefore risks selecting only high-view-count videos. Prioritizing newer upload dates mitigates this issue and enables discovery of new videos.

Figure 1 shows the upload date histogram for the searched videos. Performing two video searches revealed that the setting effectively discovered newly uploaded videos not found in the previous search. To prevent data duplication, our final list of videos only contains IDs not found in YODAS v2, allowing both datasets to be combined in future work.

2.3. Downloading

We download the videos retrieved via the search and save their corresponding subtitles and audio. Audio is always downloaded and saved at the highest possible quality, which is 48kHz multi-channel OPUS. We always download any user-uploaded manual subtitles in the video’s original language when they are available. Otherwise, we download the automatically generated YouTube subtitles in the original language. For non-English videos, we download the English subtitles as well, enabling future research on large-scale speech translation. All transcripts and translations are timestamped at the utterance level, allowing

Table 2: Examples of the metadata for each downloaded video

Metadata	Example
Channels	2
Effective channels	2
Sampling rate	48kHz
Max bandwidth	20kHz
Views	67
Language	French
Transcript	”Bonjour mes amis...”
Translation	”Hello my friends...”
Description	”Une chanson pour...”

YODAS v3 to be used for both short-form and long-form tasks. Finally, we also provide the descriptions of each video, which can be used for summarization or retrieval tasks. In general, we observed that manual subtitles were quite rare - they amount to only 3.7% of the total data (compared to 20% in YODAS v2). We hypothesize that this is a consequence of the improvements in automatic subtitling quality since the crawling of YODAS v2, making the human production of manual subtitles less necessary. An overview of the meta-data included with each downloaded audio is shown in Table 2.

3. Analysis

3.1. Language Distribution

A distribution of the data by language³ is shown in Figure 2. The top 2 languages are Arabic and Welsh, each with roughly 25K hours of data. Japanese and English are the languages with the third and fourth amount of data at roughly 21K and 17K hours. Overall, 22 languages have over 10K hours of data and 73 languages have over 5K hours of data. This highlights the effectiveness of our language-balanced video search approach (Section 2.1): the mean and median amount of data per language is 7400 and 5180 hours, respectively. Compared to most datasets, where English is often more than half of the dataset [17, 23, 33], English is less than 2% of YODAS v3.

3.2. Length Distribution

Having ample long-form data is critical for frontier audio processing tasks like conversational ASR [37], speech summarization, and dialogue modeling. In this section, we analyze the

³We use the YouTube-provided locale of each video as a proxy for language identity due to the cost of automatic language ID at scale.

Figure 2: Data distribution of the top 50 languages in YODAS v3.

Figure 3: Distribution of videos by total length (log scale), bucketed into groups by minute.

lengths of the original crawled data. Figure 3 shows the distribution of lengths per video, bucketed into minute-level groups. Overall, 1.7 million videos are longer than 5 minutes (1 million hours total) and 1.2 million are longer than 10 minutes (950K hours total). Interestingly, we observe that the curve follows a long-tail distribution, with more than 24% of the 4 million videos being less than one minute long. We attribute this observation to the rise in popularity of YouTube Shorts (short-form vertical videos similar to that of TikTok). Conversely, a manual qualitative analysis showed that a large amount of the longest videos (60+ minutes) are live-stream recordings. We leave further analysis these phenomena to future work.

3.3. True Bandwidth Estimation

We estimated the effective audio bandwidth of all recordings in the corpus, which are stored in WebM/Opus format. This step is necessary because the Opus codec always produces 48 kHz PCM at decode time, regardless of its internal bandwidth mode (narrowband at 4 kHz, wideband at 8 kHz, up to fullband at most 20 kHz). The nominal sample rate of decoded audio therefore provides no information about actual spectral content. Additionally, recordings may originate from limited-bandwidth capture devices (e.g., built-in laptop microphones, USB headsets) whose effective frequency response could fall well below their digitization rate. For each file, we computed the short-time Fourier transform (STFT) with an 8192-sample Hann win-

Figure 4: YODAS v3 data distribution by estimated effective bandwidth; over 92% of recordings exceed 32 kHz.

dow and 50% overlap. For each STFT frame, we identified the highest frequency bin whose magnitude exceeded 0.5% of the frame’s peak magnitude. Silent frames (root mean square (RMS) $\leq 10^{-6}$) were skipped. The estimated bandwidth for a recording is the maximum over all these analyzed frames. For recordings shorter than 5 minutes, the entire audio was decoded and analyzed. For longer recordings, five 60-second segments were drawn at random positions and the maximum bandwidth estimate across segments was retained. This estimated maximum frequency was mapped to the smallest standard sample rate whose Nyquist frequency equals or exceeds it, from the set 8, 16, 22.05, 24, 32, 44.1 kHz. This mirrors the classification used in the URGENT 2025 challenge [38]. The results are reported in Figure 4. We can see that most of the data (67.3%) has an effective bandwidth of 44.1 kHz and 92.5% of the data is above 32 kHz.

It should be noted that such bandwidth analysis is rarely conducted in prior dataset releases, despite being critical for understanding true audio fidelity. For instance, [38] found that CommonVoice and DNS5 LibriVox have effectively *all* samples ($\sim 100\%$ each) with mismatched bandwidths, while even LibriTTS [39] is affected in $\sim 25\%$ of samples. Our analysis confirms that YODAS v3 is genuinely high-bandwidth, making it uniquely suited for tasks that require wideband audio.

3.4. Audio Channels

We also examine if the crawled data is truly multi-channel, or if the channels are in-fact duplicates of each other. For each pair

Figure 5: Log-scale distribution of data by effective number of channels in each audio file

of channels in an audio file, we subtract them from each other and compute the Root Mean Square (RMS) of the residual normalized by the average RMS of the two channels. We apply a threshold of $1e-3$ to the result - values lower than the threshold indicate that the two compared channels are effectively identical. The distribution of results, in terms of the effective channel count, are shown in Figure 5. We find that over 71% of all audio files (about 780K hours) are truly multi-channel, with the vast majority in being stereo data. We note that there is also a small amount of data that are effectively 3-4 channels - a result of the inclusion of 5.1 surround sound audio data.

4. Experiments

4.1. Speech Recognition

Setup: We adopt a similar experimental setup to [17] for probing the quality of large-scale data by training monolingual ASR models on a random 7 language subset. We use 4500 hours for English and roughly 100 hours each for the other 6 languages. We process the data following the procedures proposed by OWSM v4 [31]: CTC-segmentation, language-based filtering, and CTC score-based filtering. We train multiple models, each corresponding to different thresholds of the CTC score quantile filter: $\theta_{CTC} = 0.00$ (no filtering), 0.10, 0.20, and 0.30. Models are initialized from OWSM v4 base 102M [31] and trained for 40K steps using ESPnet [40]. We evaluate the models on 7 languages from CommonVoice, using Word Error Rate (WER) for the 6 alphabet-based languages and Character Error Rate (CER) for Japanese.

Results: The evaluation results are shown in Table 3. Unlike prior work on filtering and cleaning YODAS v2 [31], which observed inconsistent results when balancing between data scale and filtering strictness, we find that using more data (lower θ_{CTC}) with YODAS v3 leads to improved results. In fact, WER almost always improves for all 7 languages as θ_{CTC} decreases - the best models for each language (except for English) were trained without any score-based filtering, showing that YODAS v3 is directly usable out-of-the-box. This is a large improvement from YODAS v2, which required significant filtering to avoid failed training runs (100+ WER). We hypothesize that this may be due to higher-quality automatic transcripts, which reflects the improvements in ASR performance since the release of YODAS v2 almost 3 years ago.

4.2. Neural Audio Codecs

Setup: We train neural audio codecs on a random 1200 hour subset of the data at sample rates of 16kHz, 24kHz, and 48kHz. All models use the DAC architecture [41]. Models are trained using the official configurations from the ESPnet-Codec toolkit [42], allowing for a fully fair comparison with

Table 3: WERs on different languages in Common Voice of ASR models trained on different data filtering thresholds.

Threshold	Eng.	Deu.	Fra.	Jap.	Por.	Rus.	Vie.
0.00	15.9	14.4	17.2	27.7	11.1	15.3	20.6
0.10	15.3	14.6	17.8	29.2	11.5	15.4	21.1
0.20	15.3	15.4	18.8	30.9	12.2	16.0	20.8
0.30	15.6	16.3	21.8	34.5	13.4	16.7	23.1

Table 4: Codec evaluation results. AMUSE is a multi-domain mixture for speech, sounds, and music, used by ESPnet-Codec.

Training Data	SR	LibriTTS		YODAS v3	
		STOI	SPK	STOI	SPK
<i>Baselines</i>					
LibriTTS	16kHz	0.95	0.76	0.74	0.69
LibriTTS	24kHz	0.97	0.83	0.80	0.78
AMUSE	16kHz	0.93	0.74	0.81	0.83
AMUSE	44kHz	0.95	0.82	0.90	0.77
<i>This work</i>					
YODAS v3	16kHz	0.92	0.60	0.82	0.79
YODAS v3	24kHz	0.92	0.66	0.84	0.82
YODAS v3	48kHz	0.97	0.84	0.94	0.90

models trained using existing datasets [42, 43]. Specifically, we compare against models trained on LibriTTS [43] (585 hours of English read speech) and AMUSE (33K hours of multilingual speech, music, and sound) [42]. We use the VERSA toolkit [44] for evaluation, measuring Short-Time Objective Intelligibility (STOI) [45] and WavLM embedding-based speaker similarity [46] on a 1000 video subset of YODAS v3 for in-domain testing and LibriTTS [43] for out-of-domain evaluation.

Results: All models perform worse on the YODAS v3 test set compared to LibriTTS (Table 4). This is expected since the audio domain is much more challenging - clips often have background noise and multiple sound sources. However, LibriTTS contains only clean single speaker recordings. The best performing model is the 48kHz DAC trained on YODAS v3 on both the in-domain and out-of-domain test sets with a STOI of 0.97 / 0.94 and a speaker similarity of 0.84 / 0.90, respectively. It outperforms all models trained on lower sampling rates and even models trained on more data (AMUSE, 33K hours), showing the effectiveness of the YODAS v3’s high-bandwidth data.

5. Conclusion

This paper presents YODAS v3, a weakly-supervised corpus containing 1.1 million hours of high-bandwidth stereo data across 147 languages. YODAS v3 is created using a novel language-balanced keyword search approach, allowing us to collect large amounts of data for medium and low-resource languages: 22 languages in YODAS v3 have over 10K hours and 73 languages have over 5K hours of data. We conduct several analyses on the collected audio, showing how the data is both truly stereo and high-bandwidth. Finally, we show the downstream use cases of YODAS v3. We train train ASR models are different subsets of the data, yielding results that show the cleanliness of the YODAS v3 transcripts. We also develop new high-fidelity neural codecs that are competitive with the state-of-the-art while showing how previous approaches fail to generalize to the complex audio scenes found in web-scale data.

6. Acknowledgments

Parts of this work used the PSC Bridges2 system and Delta/DeltaAI system at NCSA through allocations CIS210014 and IRI120008P from the ACCESS program, supported by NSF grants #2138259, #2138286, #2138307, #2137603, and #2138296. This paper is also based on results obtained from a project, Programs for Bridging the gap between R&D and the IDEal society (society 5.0) and Generating Economic and social value (BRIDGE)/Practical Global Research in the AI x Robotics Services, implemented by the Cabinet Office, Government of Japan.

7. Generative AI Disclosure

Generative AI was used to refine the manuscript text, such as wording and prose. It was also used to help write and scale the code necessary for large-scale crawling and data analyses. The final versions of all artifacts produced with the assistance of generative AI were created and verified by humans.
