Abstract

Background: Large language models (LLMs) have achieved performance comparable to that of physicians on multiple-choice medical knowledge examinations. However, their capabilities in clinical history taking, urgency assessment, and safety—all essential in real-world practice—remain insufficiently evaluated. We proposed Japanese Stroke LLM Evaluation, a multi-turn conversational benchmark for stroke care in Japanese, and evaluated the clinical performance and safety of LLMs under conditions designed to reflect actual practice.

Methods: We created 10 cases of stroke and related conditions, and evaluated LLMs in multi-turn conversations conducted in Japanese. The LLM acted as the physician, whereas a board-certified neurosurgeon acted as both the simulated patient and evaluator. Each case comprised a history-taking phase and an action phase, scored using pre-specified case-specific criteria. Errors that could directly threaten life were defined as critical mistakes. The rubric set an overall score of at least 80%, with zero critical mistakes as the threshold for safely supporting stroke care. A total of 18 models (nine cloud-based and nine on-premise) were evaluated in two periods: October 2025 and June 2026.

Results: Claude Fable 5 achieved the highest overall score of 87.4% with zero critical mistakes, followed by Claude Opus 4.7 at 80.3% and GLM-5.2 at 75.6%. The two leading models satisfied the pre-specified safety thresholds. Eleven models made 17 critical mistakes, including failure to confirm laboratory results or blood glucose levels before t-PA administration, proposing surgery before securing the airway, omission of cervical vascular evaluation, and proposing t-PA outside of its indication. The mean number of history-taking questions correlated positively with the history-taking score ($r = 0.648$, $p = 0.007$).

Conclusions: Japanese Stroke LLM Evaluation provides a new benchmark for evaluating the clinical performance of LLMs in Japan under conditions that reflect actual practice, including a cap on the number of history-taking questions. Quality was ensured through cases and evaluations created by neurosurgical specialists, rather than relying on an LLM-as-judge approach. Performance improved steadily across both cloud-based and on-premise models, particularly among those evaluated in 2026, with some exceeding the prespecified safety threshold. Further evaluation using real-world cases is required.

Keywords: large language models; medical benchmark; stroke; patient safety; Japanese

1. Introduction

The use of large language models (LLMs) in healthcare is rapidly expanding to include applications such as summarization of clinical records, patient communication support, triage, and clinical decision support [1]. However, the potential for misinformation or inappropriate medical advice generated by

LLMs poses significant risks, including misdiagnosis, treatment delays, or contraindicated choices. Therefore, a systematic evaluation of LLMs prior to clinical deployment is essential [1]. The medical capabilities of LLMs are most commonly evaluated through the automated scoring of multiple-choice questions (MCQs), such as MedQA [2-5], or by LLM-as-judge approaches, exemplified by HealthBench [6-9]. Although MCQs are highly reproducible, they do not readily reflect real clinical scenarios [10]. LLM-as-judge methods are also affected by self-preference and systematic biases, and continue to diverge from human evaluations; therefore, specialist human assessment remains preferable [11]. Benchmarks based on MCQs or LLM-as-judge methods have been used to support claims that LLMs outperform physicians, whereas multiturn conversational benchmarks and real-world experiments that more closely reflect clinical practice have consistently demonstrated substantially lower performance [7,12]. A recent systematic review similarly described a knowledge–practice gap: LLMs perform well on knowledge tests but substantially worse on practical and safety evaluations [13]. Assessing clinical capability requires multiturn, dialogue-based evaluations that test whether a model can actively obtain information under uncertainty and safely transition to clinical decision-making [14]. Table 1 lists Japanese Stroke LLM Evaluation among the existing benchmarks.

LLM training data are also heavily biased toward English, and the need for language- and region-specific evaluation frameworks has been repeatedly emphasized [15]. Japanese medical practice differs not only in language but also in clinical customs, including medication dosing, insurance systems, and the cultural context of patient explanations. A study that directly translated HealthBench into Japanese reported a mismatch between the evaluation criteria and Japanese clinical context [15]. Stroke care is particularly demanding because history taking, treatment, urgency assessment, and safety judgments must be rapidly integrated under time pressure, and the gap between knowledge and practice can directly threaten a patient's life [16]. To address these challenges, we developed Japanese Stroke LLM Evaluation, a Japanese-language conversational benchmark in which a physician responds as a simulated patient and a specialist engaged in stroke care performs the scoring. Using this framework, we evaluated the clinical performance and safety of 18 leading LLMs.

Table 1. Positioning of Japanese Stroke LLM Evaluation among existing benchmarks

Benchmark	Task format	Evaluator	Language
MedQA [2] / MedMCQA [3] / PubMedQA [4] / MMLU [5]	Single-turn QA / MCQ	Automated scoring	Primarily English
HealthBench [6]	Single-turn long-form response	LLM-as-judge	Multilingual
MediQ [14]	Multi-turn conversation	Automated evaluation	Primarily English
JMedEthicBench [8]	Multi-turn conversation	LLM-as-judge	Japanese
CRAFT-MD [7] / ROUNDS-Bench [9]	Multi-turn conversation	LLM-as-judge	Primarily English
AgentClinic [18]	Multi-turn conversation	LLM-as-judge	Multilingual
Japanese Stroke LLM Evaluation	Multi-turn conversation	Human evaluation by a stroke-care physician	Japanese

2. Methods

2.1 Benchmark overview

Japanese Stroke LLM Evaluation is a multi-turn conversational benchmark in which an LLM acts as the physician, while a physician responds in Japanese as the simulated patient (Figure 1). The benchmark comprised 10 cases of stroke and related conditions: three intracerebral hemorrhages, four ischemic strokes, two aneurysms, and one primary headache. Each case was scored using pre-specified criteria, with 50 points allocated to the history-taking phase and 50 points to the action phase, yielding 100 points per case and 1,000 points across all 10 cases. The rubric was designed such that correctly performing the minimum number of essential steps would yield 80% accuracy. An overall score of at least 80% (800 points), with zero critical mistakes, was specified as the threshold for safely supporting stroke care. The study design was established through discussions among three board-certified neurosurgeons. All conversations were conducted in Japanese. To minimize variations in the simulated patient role, the same board-certified neurosurgeon with 10 years of postgraduate clinical experience consistently played the patient in every session. Although the models were not blinded, comparable questions were answered consistently.

Figure 1. Structure and scoring framework of Japanese Stroke LLM Evaluation.

2.2 History-taking and action phases

After entering the common initial prompt and confirming a normal response, the evaluator presented the model with the work setting, chief complaint, and patient's age. During the history-taking phase, the LLM were instructed to ask only one item per response, with a maximum of 20 questions. In high-urgency cases, the timing of appropriate early termination of history-taking was also evaluated. At the end of history-taking, the model was required to summarize the information in a medical record before proceeding to the action phase. To standardize the evaluation, similar questions received the same answers across models, and all responses were provided by the same physician. Penalties were applied for the use of technical terminology that a patient would not know, simultaneous presentation of multiple unrelated questions, and typographical errors.

During the action phase, the LLM used the summarized medical record to propose one test or action at a time, after which the physician returned the corresponding result. Each encounter concluded when a case-specific termination criterion was met, such as referral, admission, discharge, or emergency surgery. Penalties were applied for excessive unnecessary testing and requests for tests unavailable at the facility. The full prompt used in the evaluation is provided in Supplementary Table A, and the deduction criteria are provided in Supplementary Table A2.

2.3 Critical mistakes

Critical mistakes were defined for each case as major errors that could directly affect survival. Examples include discharging a patient in whom subarachnoid hemorrhage should have been suspected; omitting laboratory testing, blood glucose evaluation, or contraindication checks before t-PA administration; prioritizing surgery over airway stabilization in a patient with intracerebral hemorrhage and airway obstruction; completing a treatment plan without evaluating a cervical vascular lesion; and proposing t-PA outside its indication. If a critical mistake occurred, the corresponding phase was assigned zero points.

2.4 Cases

The ten cases and their principal evaluation targets are summarized in Table 2. All cases were newly created fictional simulations for this study and contained no information from real patients. To ensure transparency and reproducibility, the following resources are publicly available: bilingual case descriptions, simulated-patient response rules, and scoring criteria are publicly available at <https://github.com/imy2929/Japanese-Stroke-LLM-Evaluation>.

Table 2. Case composition and principal evaluation targets

Case	Age / sex	Condition	Principal evaluation target
1	Woman in her 40s	Subarachnoid hemorrhage	Ability to distinguish subarachnoid hemorrhage from primary headache through history-taking and neurological examination
2	Woman in her 40s	Wallenberg syndrome	Distinguishing vertigo from ischemic stroke and identifying onset time and localizing symptoms
3	Woman in her 20s	Primary headache	Focused history-taking despite diverse nonspecific complaints and avoidance of excessive testing
4	Man in his 60s	Hyperacute ischemic stroke	Early termination of history-taking and appropriate hyperacute stroke treatment
5	Man in his 60s	Left putaminal hemorrhage with impending herniation	ABCDE approach, reversal of anticoagulation, and prioritization of airway stabilization
6	Man in his 60s	Ischemic stroke due to left internal carotid artery stenosis	Recognition of cervical vascular disease from scattered infarcts
7	Woman in her 50s	Impending rupture of a right internal carotid-posterior communicating artery aneurysm	Recognition of impending aneurysm rupture from oculomotor nerve palsy
8	Man in his 90s	Basilar artery occlusion	Treatment selection for a very old patient and confirmation and explanation of the wishes of the patient and family
9	Man in his 60s	Cerebellar hemorrhage	Distinguishing vertigo from cerebellar hemorrhage and recognizing the danger of posterior fossa lesions
10	11-year-old girl	Moyamoya disease presenting with intraventricular hemorrhage	Appropriate differential diagnosis and proposed treatment intervention for pediatric stroke

2.5 Models and execution conditions

The evaluation was conducted in two phases. Phase 1 (October 2025) included nine models released by September 2025: five cloud-based models (Gemini 2.5 Pro, GPT-5, OpenAI o3, Grok 4, and Qwen3-Max) and four on-premise models (Qwen3-235B-A22B, DeepSeek-V3.1, Kimi K2 0711, and gpt-oss-120b). Phase 2 (June 2026) included nine newer models: four cloud-based models (Claude Fable 5, Claude Opus 4.7, GPT-5.5, and Gemini 3.1 Pro) and five on-premise models (GLM-5.1, GLM-5.2, DeepSeek-V4-Pro, Ring-2.6-1T, and Kimi K2.6). A total of 18 models were evaluated. The models were selected based on their performance and societal relevance at the time of evaluation.

For cloud-based models, outputs were obtained through the companies' web interfaces to evaluate the best performance available at the time, with the reasoning effort set to high. GPT-5 and OpenAI o3 whose web interfaces did not allow reasoning effort specification; for these, the official APIs were used with reasoning effort set to high. For on-premise models, outputs were obtained using the OpenRouter API. The conversation memory was set to 64 turns, and all web searches were disabled to simulate use on an in-hospital server. A provider corresponding to the model developer was selected for each model. System prompts and sampling parameters were left at their default values, and reasoning was set to high, except for Kimi K2 0711, a non-thinking model. A separate chat was used for each case, and chat search was disabled for all models.

2.6 Prompt

To minimize the between-model bias, all models received the same minimal prompt with no model-specific optimization. The prompt specified the clinical roleplay workflow as follows: one question per response during the history-taking phase, a maximum of 20 questions permitted, one action per response during the action phase, and explicit recognition of the existence of critical mistakes. The complete prompts are listed in Supplementary Table A.

2.7 Statistical analysis

The association between each model's mean number of history-taking questions and its history-taking score was evaluated using Pearson's correlation coefficient. The analysis was restricted to the eight non-emergency cases, excluding Cases 4 and 5, which required emergency management. GPT-5 and OpenAI o3 were excluded because their question-count records were incomplete ($n = 16$). Statistical significance was set to $P = 0.05$.

3. Results

3.1 Overall performance

The overall performance of the 18 models is shown in Figure 2 and detailed in Supplementary Table B. Claude Fable 5 achieved the highest overall score of 87.4% with zero critical mistakes, followed by Claude Opus 4.7 at 80.3% with zero critical mistakes, GLM-5.2 at 75.6%, and GPT-5.5 at 75.5%. Only Claude Fable 5 and Claude Opus 4.7 met the prespecified safety threshold of an overall score of at least 80% with zero critical mistakes. The mean overall score of the nine models evaluated in June 2026 is 69.5%, which is substantially higher than the mean score of 48.7% among the nine models evaluated in October 2025.

Figure 2. Overall performance of the 18 models, including the contributions of history-taking and action scores and the number of critical mistakes.

Balance between history-taking and action scores varied substantially across models. For example, Gemini 2.5 Pro achieved a relatively high action-phase score (71.0%), but its history-taking score was only 46.8%. In contrast, Qwen3-Max performed poorly in both components, with scores below 50% in both phases. Some models with relatively high overall scores, such as DeepSeek-V4-Pro (64.3%), still committed critical mistakes, underscoring that the overall performance and safety must be evaluated independently.

3.2 Critical mistakes

A total of 17 critical errors were identified across 11 of the 18 models (Table 3). Nine of these occurred in Case 4 (hyperacute ischemic stroke): four models failed to confirm laboratory results before t-PA administration, one model proposed administering t-PA without blood glucose evaluation, and four models proposed administering t-PA using the Western dose rather than the Japanese dose. This finding demonstrates that the differences in clinical practice between Western countries and Japan, including t-PA dosing, can lead to serious errors [15]. Other critical mistakes included two proposals to prioritize surgery over airway stabilization, one proposal for burr-hole surgery without head computed tomography (CT) evaluation in Case 5 (impending herniation with airway obstruction), two omissions of cervical vascular evaluation in Case 6, two proposals to administer t-PA in non-indicated cases (Cases 2 and 6), and one major error in Case 9. These errors reflect a failure to maintain safety checks and

priorities that are implicit in clinical practice, such as confirming laboratory results before contrast administration or thrombolysis, applying the ABCDE approach, and evaluating the cervical vasculature, rather than simple gaps in medical knowledge. Such failures are difficult to detect using formats that score only the correctness of a single response.

Table 3. Critical mistakes by model

Model	Critical mistake
Phase 1 evaluation (2025)	
Gemini 2.5 Pro	Case 4: Administered t-PA using the Western dose
GPT-5	Case 4: Did not confirm laboratory results before t-PA administration
Grok 4	Case 4: Did not confirm laboratory results before t-PA administration Case 5: Proposed surgery before securing the airway in a patient with airway obstruction
Qwen3-Max	Case 4: Proposed t-PA without assessing blood glucose Case 5: Proposed surgery before securing the airway in a patient with airway obstruction
DeepSeek-V3.1	Case 6: Did not evaluate the cervical vasculature in a case of carotid stenosis
Qwen3-235B-A22B	Case 4: Administered t-PA using the Western dose
Kimi K2 0711	Case 2: Proposed t-PA in a nonindicated case Case 4: Did not confirm laboratory results before t-PA administration Case 6: Proposed t-PA in a nonindicated case
gpt-oss-120b	Case 4: Did not confirm laboratory results before t-PA administration Case 5: Proposed burr-hole surgery without head CT evaluation Case 6: Did not evaluate the cervical vasculature in a case of carotid stenosis
Phase 2 evaluation (2026)	
Ring-2.6-1T	Case 4: Administered t-PA using the Western dose
Kimi K2.6	Case 4: Administered t-PA using the Western dose
DeepSeek-V4-Pro	Case 9: Selected emergency-department burr-hole surgery for a cerebellar hemorrhage with little indication for surgery

3.3 Changes in error patterns between model generations

The error responses included in scoring differed markedly between model generations. Among the models evaluated in October 2025, a total of 27 hallucinations (generation of unsupported false information [1]), 41 typographical errors, and 13 self-completed responses or repetitive loops were observed. In contrast, among the models evaluated in June 2026, these counts fell substantially to six hallucinations, four typographical errors, and zero self-completed responses or loops. The error types and counts for each model are listed in Supplementary Table C. Despite this substantial reduction in these surface-level errors, three critical mistakes remained in the models evaluated in June 2026.

3.4 Association between the number of history-taking questions and history-taking score

Across the eight non-emergency cases, the mean number of history-taking questions per model was significantly and positively correlated with the history-taking score ($n = 16$; Pearson's $r = 0.648$, $R^2 =$

0.420, $p = 0.007$; Figure 3). Models that asked fewer questions, most notably, Gemini 3.1 Pro, appeared to undergo premature closure, moving to a diagnosis or treatment plan before collecting sufficient information. Conversely, some models asked numerous questions without achieving high history-taking scores, including Kimi K2.6 (mean 16.5 questions, 52.5%) and Qwen3-Max (mean: 20 questions, 61.0%). Thus, performance was determined not only by the number of questions but also by the quality of prioritization and information integration.

Figure 3. Association between the mean number of history-taking questions and history-taking score in nonemergency cases ($n = 16$).

4. Discussion

4.1 Significance of the benchmark

This study proposes a benchmark that evaluates the clinical performance and safety of LLMs in Japanese stroke care through multi-turn conversations with a physician acting as a simulated patient, and compares 18 models. Japanese Stroke LLM Evaluation has three principal features. First, it avoids the biases inherent in LLM-as-judge methods [11] by consistently using expert human evaluations conducted by a board-certified neurosurgeon. Second, it incorporates original elements, including a prespecified threshold, a cap on the number of questions, and the explicit identification of critical mistakes, to measure whether a model can make safe clinical decisions through conversation under conditions that reflect clinical practice. Third, all cases and scoring criteria were newly created from nonpublic sources, reducing the susceptibility to contamination of evaluation data into model training data, a recognized problem in public benchmarks [17]. The emergence of models that exceed the pre-specified safety threshold under these tightly constrained conditions is notable.

The knowledge-practice gap described previously [13] was clearly reproduced in this study. The overall scores varied widely, from 31.3% to 87.4%, even among models regarded as highly capable in general-

purpose benchmarks. Prominent models such as OpenAI o3 and Grok 4 remained near 60%. In contrast, the mean overall score among the models evaluated in June 2026 was approximately 21 percentage points higher than that among the models evaluated in October 2025, with Claude Fable 5 and Claude Opus 4.7 reaching the pre-specified safety threshold. These results do not establish immediate clinical readiness, but they do indicate steady progress toward safe support for stroke care. The strong performance of open-weight models that can be deployed on premises, such as GLM-5.2, is also practically important because it may enable operations without transmitting medical information outside the institution.

4.2 Premature closure and the quality of history-taking

In non-emergency cases, the number of history-taking questions positively correlated with the history-taking score. However, existing benchmarks may favor models that ask more questions or produce longer answers, a phenomenon known as verbosity bias [11]. Japanese Stroke LLM Evaluation addresses this issue by limiting the number of questions. Benchmarks that reward verbosity may poorly reflect time-constrained clinical practice. Recent benchmarks such as CRAFT-MD and AgentClinic have likewise emphasized constrained or interactive information gathering [7,18]. Premature closure, the error of committing to a diagnosis before sufficient information is collected [19], has been reported as a cause of reduced diagnostic accuracy in interactive LLM benchmarks [14]. Models such as Gemini 3.1 Pro clearly asked fewer questions, and susceptibility to premature closure may have contributed to their lower scores. Conversely, some models asked several questions without achieving high history-taking scores, indicating that question prioritization and the quality of information integration must be evaluated alongside the question count.

4.3 Critical mistakes and safety evaluation

Critical mistakes were concentrated in the omissions of safety checks that are implicit in clinical practice, including confirming laboratory results before thrombolysis, verifying the thrombolytic dose, and prioritizing airway stabilization. Failure to confirm laboratory results before contrast-enhanced CT was also observed repeatedly, although it was not classified as a critical mistake, because the order of action may vary during emergencies. Even a model with a high mean score is difficult to use clinically if it proposes an incorrect dose or a contraindicated drug, as such errors create a risk of severe harm. Therefore, evaluating critical mistakes independent of the overall score is indispensable. Because model responses are not deterministic, multiple trials are necessary to conclude that a model reliably avoids critical mistakes. Human-run trials have practical limitations, and future studies should reconsider the evaluation framework, including partial automation.

4.4 Positioning as a Japanese and non-English medical evaluation

It is noteworthy that critical mistakes related to differences in t-PA dosing between Japan and Western countries occurred repeatedly in Japanese Stroke LLM Evaluation. Performance on English-language benchmarks does not directly guarantee clinical capability in non-English environments. For example, a study that translated HealthBench into Japanese reported mismatches between the evaluation criteria and the Japanese clinical context [15]. These findings highlight the importance of developing region- and language-specific evaluation frameworks that reflect local clinical practices rather than directly applying translated English-language benchmarks.

4.5 Limitations

This pilot study included 10 cases and a single evaluator, which introduced several limitations. First, one physician at a single institution served as both the simulated patient and the evaluator, and inter-rater reliability was not assessed. Future studies should incorporate independent dual scoring by multiple evaluators and conduct agreement testing for critical-mistake judgments. Second, the benchmark

included only ten cases and one run per model. A larger case set and repeated evaluations are required. Third, when AI is used clinically as a diagnostic aid, systems that qualify as software as a medical device (SaMD) may require marketing authorization or certification under Japan's Pharmaceuticals and Medical Devices Act (PMD Act).

5. Conclusions

Japanese Stroke LLM Evaluation is a benchmark for LLMs that uses human evaluation by a stroke care physician to measure the integrated capabilities required for stroke care in Japan, including history-taking, urgency assessment, action selection, and avoidance of major errors. The evaluation of the 18 models demonstrated a steady improvement in the latest generation, as assessed in June 2026. To evaluate whether a model can make safe clinical decisions under realistic conditions, the benchmark incorporates a cap on history-taking questions, expert human evaluations, and the explicit identification of critical mistakes. Under this strict framework, Claude Fable 5 and Claude Opus 4.7 reached the prespecified safety threshold. Nevertheless, even the latest generation of models still produced critical mistakes that could threaten life. Differences in clinical practices between Western countries and Japan, particularly with respect to tPA dosing, may lead to serious errors. Therefore, before LLMs can be used to support stroke care, interactive safety evaluations specific to the regional, language, and disease domains are necessary. This study represents a preparatory investigation for real-world research. Future work should expand the number of cases and evaluators and conduct prospective validation in actual clinical settings.

6. Declarations

Conflict of Interest

The authors declare no potential conflicts of interest regarding the research, authorship, or publication of this article.

Acknowledgments

The authors thank all individuals who contributed to the development and review of the Japanese Stroke LLM Evaluation benchmark.

Funding

The authors received no financial support for the research, authorship, or publication of this article.

Declaration of AI Use

Claude Fable 5 and Sakana Marlin assisted with manuscript preparation. OpenAI Codex was used to assist with the English translation and document preparation. The authors reviewed, interpreted, and revised the final content and accepted full responsibility for the manuscript.

Ethics Statement

This study evaluated LLM performance exclusively with fictional simulated cases and included neither patient data nor interventions involving human participants; therefore, an institutional ethics review was not applicable.

Data Availability

Bilingual case descriptions, simulated-patient response rules, and scoring criteria are publicly available at <https://github.com/imy2929/Japanese-Stroke-LLM-Evaluation>.

Authors' Contributions

The first author was responsible for the study conception, model evaluation, and drafting of the manuscript. Iwamoto and Yatsushiro contributed substantially to assessing the clinical validity and appropriateness of the cases. Yatsushiro and Hirano contributed to the critical revision and proofreading of the manuscript. All authors reviewed and approved the final manuscript.

9. Supplementary

9.1 Supplementary Table A. Full Prompt

Full text of the prompt entered initially for every model. No model-specific optimization was performed.

Please role-play as a physician. Based on the conditions provided, you will now examine a patient. The examination begins with a history-taking phase. After creating a medical record, proceed to the action phase. Each phase is worth 50 points, for a total possible score of 100 points.

- Conduct all conversations in Japanese. Use of kanji characters that do not exist in Japanese will be penalized.

History-taking phase

- Using the conditions provided, take the patient's history according to the following rules.
- Ask about only one item in each question.
- You have only 20 opportunities to ask questions. Organize the history-taking in order of importance and do not ask unnecessary questions. Do not include technical terms or test names that the patient could not be expected to know.
- You are not required to ask all 20 questions. In a highly urgent situation in which treatment must begin immediately to prevent death or in which rapid action is needed to administer t-PA, end history-taking promptly after confirming the necessary items. If stroke is suspected but the situation is not immediately life-threatening, prioritize completing the history.
- Always obtain the past medical history, medication history, allergy history, and social history, including alcohol use and smoking.
- IMPORTANT: After you have finished asking questions, organize the information discussed so far and create a medical record.

Action phase

- Using the conditions provided, proceed according to the following rules.
- Present one test or action at a time. If you propose a test, the test result will be returned. If you propose an action, the result of that action will be returned.
- Avoid indiscriminate testing. However, actively perform appropriate safety checks, such as confirming laboratory results before contrast administration and obtaining routine tests before admission.
- There is no limit on the number of actions. The encounter ends when you state a designated decision such as referral, admission, or discharge home.
- Some actions are classified as critical mistakes. If you take an action that must never be performed because it threatens the patient's life, the entire action phase will receive zero points.
- If you propose a test that is unavailable at the stated facility and the test is unnecessary, a substantial deduction may be applied.

9.2 Supplementary Table A2. Deduction Criteria

A dash indicates a prerequisite or operational rule with no deduction by itself. Deductions are subtracted from 100 points for each case, and the score cannot fall below zero.

Category	Criterion	Deduction
General	100 points total (history-taking 50 + action 50). The case score cannot fall below zero.	-
General	If a critical mistake occurs, only the phase in which it occurs receives zero points. The other phase is scored independently according to the applicable criteria.	Case score = 0
General	An appropriate response cannot be generated because of a loop or similar failure.	-5 points
General	The model speaks to the patient in a language other than Japanese.	-5 points
General	Typographical error in the medical record.	-2 points
History-taking	When 20 questions have been completed or the AI indicates that it has finished, instruct it to create a medical record.	-
History-taking	Three or more unrelated questions are asked simultaneously. Respond, 'Please limit yourself to only one question.' This attempt is not counted toward the question limit. Simultaneous questions about related items, such as past medical history, are allowed.	-2 points
History-taking	The model asks about a technical term or test that the patient could not be expected to know.	-2 points
History-taking	The model asks for information that would normally already be known at the examination, such as the patient's name or date of birth. This attempt is not counted toward the question limit.	No deduction
History-taking	The model attempts to continue after 20 questions.	-5 points
History-taking	The medical record contains information that contradicts the history obtained.	-5 points per item
History-taking	The medical record omits the history of present illness, past medical history, or medication history.	-5 points per item
History-taking	The medical record omits allergy history, social history (including alcohol use and smoking), family history, menstrual history, or similar information.	No deduction in principle
History-taking	Clearly incorrect diagnosis.	-10 points
Action	The response to a proposed neurological examination differs by case: in some cases, the evaluator discloses requested findings as asked; in others, all findings are disclosed when the model requests a neurological examination.	-
Action	Multiple actions are proposed simultaneously. Respond, 'Please state only one action to take now, in chronological order.'	No deduction for the first occurrence; -5 points for each subsequent occurrence
Action	The model proposes a test that cannot be performed. Respond, 'That test is not available at this facility.'	No deduction for the first occurrence; -5 points for each subsequent occurrence
Action	The model proposes a clearly low-value test. Routine admission tests are not penalized.	-5 points
Action	A brain MRI is considered to include MRA.	-
Action	The model declares the encounter complete before the termination criterion is met. Respond, 'Please tell me what you would do next.' If the model still insists that the encounter is complete, end the case at that point.	-

9.3 Supplementary Table B. Model Performance Breakdown

History-taking and action scores were each calculated out of 500 points; the overall score was calculated out of 1,000 points (10 cases x 100 points). Reasoning effort was set to high for GPT-5 and OpenAI o3.

Evaluation period	Model	Deployment	History-taking (%)	Action (%)	Overall (%)	Critical mistakes (n)
June 2026	Claude Fable 5	Cloud	87.0	87.8	87.4	0
June 2026	Claude Opus 4.7	Cloud	76.2	84.4	80.3	0
June 2026	GLM-5.2	On-premises	71.6	79.6	75.6	0
June 2026	GPT-5.5	Cloud	71.4	79.6	75.5	0
June 2026	GLM-5.1	On-premises	64.0	77.6	70.8	0
June 2026	DeepSeek-V4-Pro	On-premises	65.0	63.6	64.3	1
June 2026	Gemini 3.1 Pro	Cloud	58.6	68.8	63.7	0
October 2025	OpenAI o3	Cloud	48.6	73.2	60.9	0
October 2025	GPT-5	Cloud	55.2	65.8	60.5	1
October 2025	Gemini 2.5 Pro	Cloud	46.8	71.0	58.9	1
June 2026	Ring-2.6-1T	On-premises	51.4	61.2	56.3	1
June 2026	Kimi K2.6	On-premises	49.0	55.0	52.0	1
October 2025	Grok 4	Cloud	46.2	57.8	52.0	2
October 2025	DeepSeek-V3.1	On-premises	37.0	59.6	48.3	1
October 2025	Qwen3-235B-A22B	On-premises	45.0	50.0	47.5	1
October 2025	Qwen3-Max	Cloud	48.8	44.4	46.6	2
October 2025	Kimi K2 0711	On-premises	22.8	41.6	32.2	3
October 2025	gpt-oss-120b	On-premises	23.8	38.8	31.3	3

9.4 Supplementary Table C. Types and Counts of Model Errors

Values are counts of error responses that received deductions. Hallucination: generation of unsupported false information. Self-completion / loops: self-completed responses or repetitive loops. Models are listed in ascending order of the combined total of hallucinations, typographical errors, self-completion / loops, and critical mistakes.

Evaluation period	Model	Deployment	Hallucinations	Typographical errors	Self-completion / loops	Critical mistakes (n)
June 2026	Claude Fable 5	Cloud	0	0	0	0
June 2026	Claude Opus 4.7	Cloud	0	0	0	0
June 2026	GPT-5.5	Cloud	0	0	0	0
June 2026	GLM-5.1	On-premises	0	0	0	0
June 2026	DeepSeek-V4-Pro	On-premises	0	0	0	1
June 2026	Gemini 3.1 Pro	Cloud	1	0	0	0
October 2025	Qwen3-Max	Cloud	1	0	0	2
June 2026	Ring-2.6-1T	On-premises	1	1	0	1
October 2025	GPT-5	Cloud	2	1	0	1
June 2026	GLM-5.2	On-premises	2	2	0	0
June 2026	Kimi K2.6	On-premises	2	1	0	1
October 2025	Grok 4	Cloud	2	0	1	2
October 2025	DeepSeek-V3.1	On-premises	1	2	2	1
October 2025	Gemini 2.5 Pro	Cloud	3	3	0	1
October 2025	OpenAI o3	Cloud	9	0	5	0
October 2025	Qwen3-235B-A22B	On-premises	1	9	4	1
October 2025	gpt-oss-120b	On-premises	4	11	0	3
October 2025	Kimi K2 0711	On-premises	4	15	1	3
